PROFESSION AND HE GENERAL MEDICAL CO CIL.

JAMES GREY LOVER, M.D.,
L.R.C.S. EDIN., L.S.A.,
ECT REPRESENTATIVE FO ENGLAND AND WALES IN THE
AL MEDICAL COUNCIL.

FELLOW PRACTITIONERS,—The Editors of THE LANCET have kindly placed at my disposal a few valuable columns of their space that in a New Year's Address I may put myself into communication with the profession in England and Wales which I have the honour to represent in the General Medical Council. I have always been of opinion that the chief way in which his constituents can judge as to how a Direct Representative discharges his duty is by reference to the part he plays and the work he does on the Council, but the absence of frequent opportunities of addressing any large number of one's constituents directly at any length on matters affecting the profession makes the use of occasional opportunities of doing so as agreeable to me as it is respectful to you.

I have headed my address "The Profession and the *General Medical Council*" According to my view the profession is much greater than the General Medical Council and the Council is only great in proportion as it reflects and represents all that is best in the profession. True, it is supposed not to represent the profession *only*, but the State in its relations to medicine—relations which are growing in number and in gravity every day and which have no slight bearing on the subject of Direct Representation as I shall hope to show. I think the present moment is a peculiarly fit ne for reviewing our legal position and considering where we are and what is our duty as a profession. Two or three osecutions under the Medical Acts have lately taken ice in which to ordinary lay minds the accused persons d glaringly violated the penal clauses. I refer particularly the case of Matthews at Norwich, the Eastburn case in Scotland, and last of all the case of Steel in the county of Durham. The boldest champion of the sufficiency of the existing Acts may well begin to have misgivings and we are all practically agreed that the amendment of the Acts has become urgently necessary if the profession and the public are not to be injured grievously by the defiance of the most arrant quacks under cover of law aping all the functions of medical practitioners, including that of giving certificates of all sorts and quasi-certificates of death, which are accepted generally by the Registration department of the State. This monstrous state of matters is not the only reason why we should seek an amendment of the Medical Acts and review the relations of the State to the profession. There re others. The complete breakdown in the legal provisions or securing universal vaccination and of the public arrangements for teaching students how to vaccinate are among the ost grave facts of recent history. In spite of the compliments aid, and honestly paid, by leading statesmen to the medical rofession it has still to fight for the due recognition of its rights and of its authority as a factor in legislation. I tried o show at the recent meeting of the General Medical Council ow much depends in the present crisis of vaccination lawlessness on the private and quiet influence of the medical ofession, and I have no reason to complain greatly that the asideration of this view was rather deferred than rejected members of the Council and by Sir Richard Thorne himlf who naturally believes in the high official view of this great public question. But the full effect of this quiet influence of the profession through its general practitioners is hindered by the small number of such practitioners on the Council as Direct Representatives in proportion to the overwhelming numbers representing teaching and examining bodies. The effect of this "disproportion'd sin" is constantly felt by the Direct Representatives, the more so as there is no direct epresentation of members in the councils of the individual ualifying bodies and but a very indirect and ineffectual representation in the councils of the universities. No opportunity should be lost of introducing the principle of direct representation into the government of the individual bodies and of extending the direct representation in the General Medical Council. It is only by such extension of the principle that the agitation of those who advocate it can be allayed and that the full and beneficial influence of the profession as a whole can be brought to bear on medical education and on legislation for such amendment of the medical acts as is admitted on all hands to be necessary.

There may be differences of opinion as to the best means of securing the fuller representation of the profession in the General Medical Council. Some advocate a change in the law defining the individual bodies as consisting of Licentiates, Members, and Fellows, or, in the case of the universities, of the whole body of graduates. By this change it is supposed that the practitioners of the country would make themselves felt more effectually in the Government alike of the individual bodies and of the General Medical Council Others look rather to such changes in the charters or in the law as shall introduce direct representation into the medical corporations and extend it in the case of the General Medical Council. My own belief is that the reform will come sooner in the way of direct representation, which having been already conceded by Parliament in the case of the General Medical Council cannot reasonably be withheld in the case of the individual bodies. That the governing councils of these bodies should set themselves against such a reform has always surprised me. The opposition is a survival of the feelings which ruled in the Medical Corporations eighty years ago and which were expressed by Mr. Abernethy as an answer to the just demands of Mr. Wakley and his followers for a reform of the constitution of the Royal College of Surgeons of England. The following words occur in the course of a document presented by Mr. Abernethy and entitled, "Observations in Refutation of Charges publicly made by certain Members of the College against its Legally Constituted Authorities."[1]

"It is represented that the constitution of the College has been the cause of the alleged injuries and grievances.

"The evident object of this representation is the subversion of the present government of the College and the substitution of elections to offices of control and responsibility by members who for the most part exercise the professions of apothecaries and accoucheurs. There can be little doubt that in the event of such an innovation the Institution would soon cease to be a College of Surgeons or of Surgery, and a system of continual intrigue and cabal amongst the profession in general would be introduced."

The existence of such feelings in the heads towards the rank and file of the profession two or three generations back was bad enough; it is now quite indefensible when the apothecary is also a surgeon in the eye of the law, if not a physician also—a point upon which we may have soon an authoritative legal deliverance—when there are no fine lines of demarcation between the different grades of practice, when the difference in the severity of the examinations of the various examining boards is less, and when degree and diploma alike constitute a licence to practise the art of medicine in all its three equal branches. Surely the time is fully come for the governing bodies of our great corporations to do tardy justice to their own members by giving them a voice in the management of their own corporations. Such an act of justice would do more than anything else to harmonise the profession and to raise it in the estimation of the public. It cannot be expected that the public should treat the profession with due respect when universities give their graduates and medical corporations give their members so little function, denying them, as a rule, all "offices of control and responsibility."

The feelings of distrust and disrespect towards the rank and file which are expressed in Mr. Abernethy's Refutation surviving still in the corporations almost necessarily survive in the General Medical Council which is made up so predominantly of the representatives of corporations and universities. But I have been long enough a member of the General Medical Council to believe that they are undergoing insensibly a considerable modification and that with a little more mutual consideration between Official and Direct Representatives a very valuable amount of harmony and cooperation between different sections of the profession would be reached which would tell immensely in advancing medical education and the social and political position of the profession.

---

[1] THE LANCET, May 30th, 1836, p. 1514.

It is only fair to say that even with its present constitution the General Medical Council has done something for the profession. It has, with a few regrettable exceptions, given a fair and respectful hearing to the Direct Representatives, it has put them into its various committees and its offices of trust, and it has well-nigh abolished the unqualified assistant. It has presented to the Government a unanimous report on the principles which should regulate legislation on midwives. If these should be adopted by Parliament "quacks" will be abolished, the practice of midwives will be regulated by a board and all doubtful "labours" will quickly be brought under the notice of a registered medical practitioner. The General Medical Council has started fairly on a course for securing a fit preliminary education for those entering the profession. No doubt the Council has been late and long in accomplishing some of this creditable work, but let us generously admit that it has done it and that the chief promoters of it have not all or always been Direct Representatives, though these have taken an important part, and on one memorable occasion had their valuable work somewhat rudely appropriated by others. The General Medical Council further has slowly constructed a set of Standing Orders regulating *inter alia* the procedure of the Council in its penal action against any accused *member of the profession and requiring that such accused* person shall be supplied with "the particulars" of the charge against him. It has lately, on the motion of Sir Batty Tuke, resolved that no case of complaint shall be considered by the Penal Cases Committee until a statutory declaration as to the facts of the case has been supplied by the complainant. Finally, the General Medical Council with all its faults has some interesting features compared with other medical authorities. Firstly, it is the only medical body which acts openly. Its discussions with few exceptions are open to the public and are reported by the medical press and by a considerable section of the lay press. Secondly, the General Medical Council is in its composition a broad and comprehensive body. It represents all the medical authorities, the Crown, and, though imperfectly, the registered practitioners of the Empire. I would gladly see it a smaller but I should be sorry to see it a less representative body than it is.

These are a few features of the Council which make it an interesting body. However critical we may be we can afford to recognise them and admit that they tend to benefit the profession as well as the public. We may go further and admit that the profession has been benefited. I shall immediately speak of matters needing reform, but I should think it impolitic and unjust to be pessimistic in tone in speaking of the condition of the profession now as compared with the period before the establishment of the General Medical Council and not to recognise improvements in the status of the profession. The numbers in the profession are excessive, but the openings for medical work in the empire have been greatly multiplied by its growth and by reason of the development of sanitary legislation. It is difficult to compare the position of the medical practitioner now with that position prior to the Medical Acts. We are all apt to be oblivious of the grievances of former days and to place our predecessors in idyllic conditions. But I should be sorry to exchange the conditions of the present day with those of the ante-Medical Acts period. There are many hardships now, but they will compare favourably with those of the former period, and I believe the position and the prospects of the medical man who does not adopt pessimistic theories to be better now than it was then. But with every disposition to allow that the General Medical Council is an interesting and useful body and that its action has been such as to improve the education of the profession and its status generally, I must point out in conclusion some much-needed reforms in its own constitution and functions and in the penal clauses of the Medical Act.

THE CONSTITUTION OF THE COUNCIL.

It is too large and it is not sufficiently in touch with those general practitioners for securing the competency of whom it exists. Some of its most eminent members have said almost boastfully that they have never attended a midwifery case. A body which has generally met the demand for an increase in Direct Representation with the blank proposal of the previous question must be defective in its sympathies with a profession from which it derives its own honour
creation of the Conjoi
1886 as the first step
which there will not b

THE FUNCTIO

The supervisory duties of
medical education and the standard of exa
reference only to the maintenance of a minimum standard securing a bare competency to practise. The Council has no power to inspect examinations of a higher class as such or pretending to be of a higher grade. It seems obvious that some body of the profession should have the power and duty of inspecting and reporting on the nature of such ostensibly higher examinations, carrying generally at any rate higher titles than attach to the ordinary diplomas. Surely no body can so fitly be endowed with such powers as the General Medical Council in which by its very constitution all bodies are represented.

THE LAX STATE OF DEATH REGISTRATION.

One of the most urgently needed pieces of legislation is that which would make it essential for the registration of a death to have either the certificate of a registered medical practitioner or that of a coroner as to the cause of death. Pending such legislation there are large districts in which a statement of the cause of death by a herbalist or any other quack seems as valid for registration purposes as the certificate of a medical man. The Council has taken, partly at my instigation, much trouble to bring this amendment about. The President (Sir William Turner) has been most painstaking in his communications with Government. So far nothing effective has been done. But the Council is still vigilant and active in the matter.

THE PENAL CLAUSES OF THE MEDICAL ACTS.

I have already referred to the glaring inefficiency of the 40th clause of the Medical Acts as illustrated in the cases I have mentioned. The failure in some of the cases may have been due to the faulty way in which they have been prepared, but this will not suffice to explain all. The uncertainty of getting a verdict is so great as to invalidate the Medical Act of 1858 in its chief purpose—viz., that of "enabling persons requiring medical aid to distinguish qualified from unqualified practitioners." To facilitate such a distinction is surely the very least that law can do for a profession on which it lays such heavy burdens of education and duty. It should do much more. It should punish not only the assumption of all misleading titles by unqualified practitioners but all practice by them as being essentially against the public interest. Apart from legislation or any change in the constitution of the General Medical Council there are reforms of procedure, penal and general, which would expedite the Council's business. I supported most of the proposals to this effect by Mr. Horsley at the late meeting. I have long urged an enlargement of the Penal Cases Committee and more frequent meetings of it—so far unsuccessfully. Mr. Brown advocated the delegation of the penal business, in the first instance at least, to the Branch Councils. I supported this proposal. But so far we have not succeeded in any plan for making this committee so large and representative as it ought to be. We have, however, succeeded in making it liable to change by annual election.

On the whole I am not hopeless of considerable reforms, even with the present constitution of the Council. But if they are to be achieved two things are necessary. First, that some attempt be made to secure union in the Council and in the profession. If this cannot be procured we may give up all hope of any help from Parliament or Ministers. Unless we appeal to Parliament with a united front we had better abandon all hope of legislation. Next to union in the Council and in the profession our best hope of amendment in the Medical Acts is in making practical proposals. The extreme reformers and the extreme admirers of things as they are neutralise each other and stop all progress. Parliament is heavily handicapped with work and has a great dislike to undertake medical legislation

A Clinical Lecture

ON

SOME PECULIARITIES IN THE BEHAVIOUR OF CERTAIN MALIGNANT AND INNOCENT GROWTHS.

Delivered at St. George's Hospital

By WILLIAM H. BENNETT, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL; JOINT-LECTURER ON SURGERY IN THE
MEDICAL SCHOOL; MEMBER OF THE COURT OF EXAMINERS,
ROYAL COLLEGE OF SURGEONS OF ENGLAND; EXAMINER
IN SURGERY AT THE UNIVERSITY OF CAMBRIDGE,
ETC.

GENTLEMEN,—There is probably no subject of greater interest to the practical surgeon than the peculiarity which is sometimes seen in the behaviour of certain tumours, especially those which are apparently malignant. The question is one about which little is definitely known; it is, however, of considerable importance in relation to prognoses and treatment and is therefore worthy of some attention. During the past few years the uncertainty which attaches to the course of some of these cases has been brought prominently before me by a succession of instances in my practice some of which I propose to describe in the present lecture with a view to arriving at some practical conclusions. With this object the cases may be usefully divided into three classes: (1) those illustrating the occurrence of tumours which, although apparently malignant, run an innocent course; (2) examples of the occurrence of tumours which, being apparently innocent, prove in the end to be malignant; and (3) cases illustrating the influence of the concentration of the mind of the patient upon the part, in the growth of innocent tumours or in the development of malignant disease.

TUMOURS APPARENTLY MALIGNANT WHICH RUN AN INNOCENT COURSE.

Cases in this category are of two kinds: (1) those in which the growth entirely disappears spontaneously; and (2) those in which it becomes quiescent, assuming a condition which may be conveniently termed "negative malignancy." Each of these classes again consists of two sets of cases—those in which the malignant character is verified by the evidence of the microscope and those in which clinical characteristics alone determine the diagnosis.

TUMOURS APPARENTLY MALIGNANT WHICH ENTIRELY DISAPPEAR SPONTANEOUSLY.

Class 1: The Nature of the Growth Verified by the Microscope.

CASE 1.—A woman, aged thirty-six years, was sent to me on account of an abdominal tumour. It was stated that she had been in good health until her last confinement nine months previously. Although she had had a "bad time" at the confinement nothing happened until a month or two afterwards, when, as she did not appear to regain her usual state of health and complained of abdominal discomfort, an examination was made, with the result that a hard mass was discovered on the right side immediately below the liver. This mass slowly increased and the patient, who was previously robust and rather stout, became weak and greatly emaciated. From time to time there had been a discharge of mucus and slime from the bowel and increasingly obstinate constipation supervened. When I first saw her she was thin and wasted to an extreme degree, the skin over the abdomen was wanting in elasticity; the face was sallow and the general aspect of the patient was that of malignant cachexia. A little to the right of the middle line under the liver was a mass somewhat fixed, irregular in outline, and moving a little with the liver in respiration; over a spot towards its inner side it was very sensitive to the touch. Although in some respects the case was most unpromising it was thought wise in view of the possible onset of intestinal obstruction to make an abdominal exploration. Upon opening the abdomen a large nodulated mass of stony hardness was found in the situation indicated. It appeared to invade the liver, on the upper surface of which, quite distinct from the main tumour, was a roundish nodule of the size of half a walnut of a characteristic malignant appearance; the omentum was involved in the mass and tucked up so that it formed merely a hard compressed irregular lump. To the naked eye the tumour was beyond doubt malignant, but as the growth had been slightly torn in the manipulation a portion was excised for microscopical examination and was subsequently reported to be a typical specimen of mixed round- and spindle-celled sarcoma. The recovery from the immediate effects of the operation was rapid and the gravest possible view having been taken of her case the patient was sent home in the full belief on my part that the remainder of her life must be measured by months only. She did not, however, die, but gradually improved in condition and in eighteen months was a healthy, well-nourished woman in whom no trace of a tumour could be found.

CASE 2.—A woman, aged fifty-two years, was admitted into St. George's Hospital early in 1896 on account of a well-marked melanotic sarcoma of the sole of the foot which was freely excised, the wound healing in the ordinary way. In August of the same year she was admitted under my care with extensive recurrence, for which Symes's amputation was performed on Aug. 18th. On Sept. 19th some small blackish tumours were noticed on the skin along the inner side of the thigh; these increased in size and multiplied until they reached the number of 62. At the same time some hard glands began to appear in Scarpa's triangle; one of the skin nodules was removed and was found to be a typical round-celled sarcoma *without pigment*. The original growth was a well-marked melanotic sarcoma and the recurrent disease of the same kind but less pigmented. A formal consultation was held with regard to the future treatment of the case and it was naturally decided that in a patient who showed such an extreme tendency to dissemination of the disease no further operative measures could achieve any useful end. The case was therefore regarded as hopeless, the patient being recommended to go to the parish infirmary to pass the brief remainder of her life in as much comfort as was practicable. This, however, she declined to do and went to her home. Six months later she came to the hospital in excellent health; the stump was an extremely good one and all the nodules in the thigh had disappeared with the exception of three or four which were hardly perceptible and no enlarged glands in Scarpa's triangle could be felt. She again presented herself subsequently, every trace of the nodules having gone, and when last seen she was in perfect health in all respects.

CASE 3.—I have seen another case exactly similar to the above excepting that the original growth was on the outer side of the dorsum of the foot, the nodules being disposed along the outer side of the leg and the enlarged glands situated in the popliteal space. Spontaneous disappearance of the nodules and gland followed removal; the nodules on the skin were unpigmented.

CASE 4.—This in some respects is one of the most remarkable which have come under my observation. A man, aged forty eight years, consulted me concerning what was thought to be a hydrocele. The tumour was not larger than an orange and was less oval than usual in hydrocele. It was stated to have existed for nine years, having practically been unchanged in size for the last seven of these. About six weeks before I saw him he had received a slight blow on the tumour which made it a little sensitive. It was tapped after it had existed for five years and a small quantity of clear fluid was said to have come away without causing any material diminution in the size of the swelling. The tumour was opaque and did not to my mind suggest hydrocele, but the patient would have no interference and, indeed, merely consulted me for advice about the most suitable kind of suspender for the trouble. A year later he came again as, although no increase in size had taken place, he was unable to obtain a satisfactory support. He was therefore anxious for tapping in order to make the thing more manageable. Although I did not expect to effect much by the tapping I introduced a small trocar deeply into the mass which was quite insensitive; a little blood only came away. The tumour clearly was quite solid and having considered the circumstances generally I advised its removal. This course the patient declined unless the malignant nature of the growth could be demonstrated with certainty. As the tumour was so insensitive I introduced a large trocar and cannula and by moving the end of the cannula freely in the substance of the mass succeeded in bringing away some tissue which upon microscopical examination presented appearances characteristic of sarcoma. I feared fungation from the trocar wound, but this healed rapidly and castration having been postponed for a period the tumour slowly decreased in size and in three months had lost half its bulk. I heard subsequently that the testicle had become "very much like the other one, but was quite numb."

CASE 5.—The only case resembling this of which I have heard was one in which a tumour in the scrotum, about the nature of which there was some doubt, was punctured by a fine trocar and cannula and a few drops of blood were withdrawn; a diagnosis of sarcoma was made and removal was advocated, but the tumour slowly disappeared spontaneously after the puncture. No microscopical examination was made but the case was probably of the same nature as the one which I have described.[1]

Class II: The Nature of the Growth estimated by its Clinical Characteristics only.

CASE 6.—A middle-aged man was admitted into St. George's Hospital under the care of Dr. Ewart in August, 1893, on account of pyloric obstruction due to a large growth. He was in the last stage of emaciation and had the cachectic appearance often associated with malignant disease. After a consultation with my colleagues I performed abdominal section and exposed a mass nearly as large as a man's fist involving the pylorus. In the omentum were several hard nodules and under the liver were nodules of a similar kind. The main tumour was of stony hardness, the nodules which were freely manipulated not only by myself but by my colleague, Mr. Dent, who was present at the operation, being equally hard. The appearances of malignant disease were so clear that it was not thought worth while to remove anything for microscopical examination which I now greatly regret. Gastro-jejunostomy was performed. Not only did a rapid recovery from the immediate effects of the operation follow, but the tumour steadily decreased in size until it was imperceptible. The man is still alive and in fair health, the operation having been performed five years and four months ago. The case is additionally interesting from the fact that it is, I believe, the only instance on record in which a patient has survived so long after gastro-enterostomy for what appeared to be undoubted malignant disease.

CASE 7.—A female patient, of middle age, was sent to me on account of a large tumour in the lower part of the neck. She was well nourished but her aspect was somewhat anxious and inclined to sallowness. The skin generally was inelastic, especially about the root of the neck on the sound side. On the right side of the neck low down was a mass apparently glandular which was quite fixed at its lower part, where it extended under the clavicle, becoming continuous with an area of dulness behind the upper end of the sternum. The tumour was insensitive to pressure and excepting its mere existence caused no trouble. There was neither dysphagia nor dyspnœa but over the upper part of the acromion there was an area of anæsthesia as if one of the descending branches of the cervical plexus had been involved. So far as its clinical aspects were concerned the mass seemed undoubtedly malignant and probably secondary to some deep primary lesion. The ultimate result seemed certain and the case was obviously outside the limits of justifiable surgical interference. I therefore wrote to that effect to the medical attendant, but added that from wh
cases I should not be sur
spontaneously. A few
had become stationary, a
quently shrink and pr
recently that the patie

Of cases of tumours
clinical characteristics
taneously I might gi
described are, howeve suffi

TUMOURS APPARE LY ALIGNANT, QUIESCENT, SU NG A CONDITION NEG MALIGNANCY.

In the examples oth category I do not propose to include the shrinking at phic cancer of old age but shall confine myself to cas o growths which, originating in middle life when the itutional powers are vigorous, become after a period activity perfectly passive, neither diminishing nor increa in bulk and causing no pain or other symptom indica of life in them. Microscopical evidence of malignan must of necessity be difficult to obtain in such cases ce they are usually those which escape operation either exploratory or curative purposes. The majority of the cases occ in the female breast, but they are seen elsewhere, more esp lly in malignant disease of the glands.

CASE 8.—A man, aged forty years, was admitted into St. George's Hospital under my care in June, 18 on account of a tumour of the right testicle of nine months growth. The disease seemed obviously malignant and no secondary deposits were found upon his admission. Castration was performed early in July and the growth proved to be "encephaloid carcinoma." The operation wound healed immediately and no abnormal rise of temperature occurred. A week subsequent to the operation a hard mass was indistinctly felt below the liver passing towards the loin. A little later a hard mass developed in the iliac fossa; it was fixed and presented all the clinical characters of a mass of malignant glands. The masses increased in size, but were painless. The temperature was normal and no inflammatory symptoms of any kind were present. The case was regarded as hopeless and the patient left the hospital to go to the seaside where, although he seemed to improve in general health and nutrition, the tumours continued to increase. Six months after the operation there was extensive painless œdema of the right lower limb clearly due to the pressure of the iliac mass; the left lower limb was also slightly swollen; the urine was normal. When I saw the man in this condition I naturally thought that his end was not far off. In this, however, I was mistaken, as about four months later he again showed himself in better health than he had been in since the operation; the œdema of the lower limbs had entirely gone, the mass in the iliac fossa was hardly perceptible, but the sub-hepatic tumour could still be plainly felt. He came under observation again two months later, when the iliac mass had disappeared, whilst the other tumour above had shrunk to about the same size as when it was first discovered. He was specially asked to report himself again if he became worse, but I have heard nothing further of him.

CASE 9.—In 1893 I removed the left mamma of an unmarried woman about thirty-six years of age, on account of a tumour which proved to be a slowly growing scirrhous carcinoma. She remained well until 1896 when the opposite breast showed evidence of malignant disease; it was therefore removed and upon examination it showed a large number of involution cysts and a mass of rapidly growing scirrhus of the size of a walnut. The patient was of splendid moral fibre and placid in disposition; she appeared to attach little or no importance to the disease, so much so that she did not inquire as to its nature and resumed her ordinary occupations and amusements after each operation with commendable energy. Soon after the second operation some hard nodules appeared along the scar of the first operation wound. These were followed by others in the skin of the typical carcinomatous aspect; there were about a dozen in all, the hindermost nodule being only a little in front of the scapular angle. To these she paid no attention. I have recently seen her in perfect health; all the nodules have disappeared excepting one close to the middle of the scar which appears quite harmless. This case affords the nearest approach to the complete spontaneous disappearance of carcinoma which I have up to the present seen.

---

[1] This case should come in the next class but more conveniently follows immediately upon Case 4.

operation often depress the patient an constitutional power of resistance, brtail because the nature growth in the process of remov verified by the micro- cancer juice (I the term not oöphorectomy or any other but because it conveys a ver in the last case it would have possible result of a direct e example of the success of the there is, so far as I a show that in cases of at the age of thirty-six years became where they most c umour in the right breast which a sur- in any way m ed whose judgment in such cases may be disease. allible pronounced to be scirrhus. From the The truth is when first discovered it increased to the size the removal o in about eighteen months. It then became slightly smaller and more flattened in shape, the skin at the same time being drawn in towards the tumour. I saw her fifteen years after the original appearance of the disease and she declared that no change of any kind had occurred in that time; she merely consulted me on account of a small boil in the axilla which she thought might possibly be connected with it The patient was stout and healthy-looking; the tumour was characteristic, freely moveable upon the parts beneath but the skin was adherent over it. As it was at the extreme axillary margin of the breast it might easily have escaped notice altogether. I saw the tumour again five years later; it was unaltered. The patient remained in excellent health until the formation of an acute abdominal abscess, probably pericæcal, which terminated fatally.

It would be easy to give other examples of this kind which I believe are more common than is generally supposed.

CASE 11.—Amongst those cases of which I have had personal experience was that of an old lady who died at a great age with a characteristic scirrhous mass in the right breast which from unimpeachable evidence had remained unchanged for many years.

TUMOURS APPARENTLY INNOCENT WHICH RUN A MALIGNANT COURSE.

Recurrent tumours originally innocent which in the course of years become malignant are not rarely met with—for example, I have recorded a case in the Transactions of the Clinical Society of London in which an innocent fibrous naso-pharyngeal polypus became in the course of about twenty years malignant and finally led to the patient's death. With cases of that kind I am not at present concerned, as in those which I have here in view the change from innocent growth to malignancy is rapid.

CASE 12.—A woman, aged about thirty years, was admitted into St George's Hospital in February, 1898, with a pedunculated dusky tumour springing apparently from the gum close to the socket of the left anterior molar tooth which had been extracted a few months before. The growth was not larger than a horse-bean and gave rise to no trouble excepting constant bleedings which followed mastication. The appearances were consistent with epulis and the tumour was therefore removed as freely as possible, the actual cautery being thoroughly applied to its point of attachment. Upon microscopical examination the tissue removed was reported to consist merely of granulation tissue. The patient was discharged about the middle of March. In October she presented herself at the hospital again. In the site of the original tumour was a hardish mass of the size of a small walnut which seemed to sprout from the margin of the jaw which was somewhat expanded. No trouble beyond the bleeding similarly associated with the original growth was complained of. A portion of the tumour now removed was reported to be typical of myeloid sarcoma. The mass, together with the portion of the jaw from which it sprang, was removed. No tendency to recurrence has since shown itself In this case it will be seen that a perfectly innocent type of new growth was succeeded by a sarcoma in less than six months.

CASE 13—A man of fine physique, forty-two years of age, consulted me with the following history. For a year or more he had been troubled with nasal polypi which had been removed by the surgeon who brought the patient to me In consequence of the rapid recurrence of the polypi and because they seemed to project into the nose through the opening from the antrum they had been submitted to microscopical examination, with the result that they were pronounced as innocent mucous polypi of the ordinary kind. The cause of a further opinion being sought was a bulging which had recently appeared above the alveolar margin on the left upper jaw which was to my mind suggestive of malignant disease. Electric illumination of the antrum showed nothing positive; it was therefore decided that the bulging portion should be incised for exploratory purposes with the object of obtaining further material for pathological report. At this time beyond the bulging of the jaw above the alveolus there was no evidence of any kind of intra-antral tumour. The exploration was duly made by the surgeon in whose charge the patient was, a little viscid fluid escaping upon the making of the incision; this together with some gelatinous material which was taken away was submitted again for examination, but it afforded nothing in the least suggestive of malignant disease. Shortly after this a polypoid mass was again removed from the nose, but it was much more fibrous in consistence than the previous polypi. Again, the microscope showed no positive evidence of malignancy, Within six weeks of the bulging of the alveolar border referred to there was distinct evidence of antral tumour and I removed the jaw. I can safely say that I have never had to do with a tumour of the upper jaw of a more malignant aspect. The whole bone was soft and infiltrated. Its removal as a whole was out of the question; it was taken away piece by piece. The tumour which evidently sprang from within the antrum was of the consistency of blood clot. The result of microscopical examination of the tumour thus removed was inconclusive, for although the structure of the growth was compatible with sarcoma its variation from the type of innocent tumour was not great, so that a fair prospect of freedom from recurrence was held out. The tumour which had been most freely removed recurred almost before the operation wound had healed, and the patient died partly from exhaustion and partly from symptoms of cerebral tumour within six months.

CASE 14.—A man, aged thirty-three years, was admitted into St George's Hospital in April, 1898, on account of some "stuffiness" about the back of the throat, inability to breathe through the nose, and occasional epistaxis. Upon examination the naso-pharynx was occupied by a softish nodulated mass which bled moderately after manipulation. As its nature seemed doubtful a fair-sized piece was removed for microscopical examination and was reported to present the appearances of lymphoid tissue only. An operation was therefore performed about a fortnight later as if the case were one of adenoid growth, a large quantity of soft material being removed in all respects identical with the portion previously submitted for microscopical examination. The report upon this was to the effect that although its nature was somewhat doubtful it was compatible with sarcoma Immediate recurrence followed, extensive glandular enlargement in the neck succeeding.

CASE 15—I removed from the leg of a female patient, aged about fifty years, a scar resulting from an injury received twenty years before which had become hard and nodulated during the previous six months; the disease had all the appearances of epithelioma. Upon microscopical examination it was reported to consist purely of fibrous tissue without any evidence of malignant structure; many sections were examined with the same result The patient was therefore assured that the condition was harmless. Within six months of the operation a small nodule appeared at the upper end of the wound; it was a typical specimen of squamous carcinoma.

MENTAL CONCENTRATION UPON A PART AS A FACTOR IN THE INCREASE OR DEVELOPMENT OF NEW GROWTHS.

The tendency of general mental worry towards the development of certain diseases in persons predisposed to them is a matter of common knowledge, the cause in all probability being the resulting diminution in the normal powers of resistance. Little attention has, however, from a surgical standpoint been paid to the effects of continual concentration of the mind of a patient upon a particular site already affected by some abnormal condition. The interest in the matter is not only abstract but it has a practical side of some importance. The following cases will indicate exactly what I mean by the effects of mental concentration.

CASE 16—A woman, aged thirty-six years, had a small fibro-adenoma on the right breast which had existed for ten years and had undergone no change whatever from the time of its discovery by accident when she was twenty-two years old. It was regarded as being of no consequence; in fact, so little importance did the patient attach to the matter that she said she had really forgotten its existence She was not a nervous subject in the ordinary sense but was rather easily impressed with the importance of any subject if forcibly brought to her attention. In conversation with a friend on a certain occasion she was reminded of the tumour and mentioned its existence. Her friend at once appeared much concerned and advised her to seek advice at once or "cancer might result." The word "cancer" alarmed her greatly and appealed to the impressionable side of her disposition. From the time of this conversation she assured me that although she refrained from seeking professional advice her thoughts were seldom if ever removed from the tumour, night after night she lay awake thinking of the terrible possibilities of the lump to which she had previously hardly given a thought. At the end of a fortnight she noticed some pricking pain about it and a month afterwards when she consulted me after a long interval it was certainly as large again as when in its original condition. In spite of reassurances the mental attitude remained unaltered and the tumour continued to increase and was removed. It was an ordinary fibro-adenoma and with the assurance of its *innocence* after its removal the patient's apprehension was allayed and no further trouble has arisen.

CASE 17.—This is a much more striking instance. A woman, aged about forty years, who had every cause to fear cancer from her family history and other reasons, developed a small cystic tumour in the right breast, at the discovery of which she was greatly alarmed. I have never seen such an exaggerated degree of fear with regard to cancer in any patient. The tumour was removed and proved to be, as was expected, a perfectly innocent cysto-adenoma of the common type. In spite of all reassurances the fear of cancer prevailed and the patient thought of nothing else by day and night beyond the possibility of the disease attacking the spot from which the tumour had been removed. Her mind was, in truth, continually fixed upon the spot and she told me that even when at the theatre or in society, &c., her thoughts were really never removed from the site of her trouble. The scar, otherwise perfectly healthy, became at the end of a month sensitive and she complained perpetually of shooting pain about it. Six months later a hard, indurated mass had developed in the breast at the outer side of the scar from which it was inseparable, the skin being puckered over it. The breast was removed a little later and the growth was a typical scirrhus of rapid growth.

It may of course be said that there is nothing beyond coincidence in these cases and had they been the only equally marked instances with which I have met I should probably be inclined to that view, but I have seen some other equally clear examples like the first case and one other like the second whilst at the present time I have under observation another case which seems likely to end in the same way.

REMARKS ON THE FOREGOING CASES.

In the cases which I have described there is nothing intrinsically remarkable; any surgeon of considerable experience could probably produce an equally characteristic series. Many instances of spontaneous disappearance of abdominal tumours presumably malignant have been from time to time recorded, although in the majority the results of microscopical examination were for sufficient reasons not forthcoming, but I am not aware of any set of cases of so comprehensive a kind as the present having been published. In their selection care has been taken to exclude those in which syphilis or tubercle could in any sense be considered a possible factor and such changes as occurred were quite independent of any medicinal treatment. In the cases in which the disease was subjected to pathological examination it is clear that the microscope was powerless to indicate their future progress although the anatomical characters were plain enough and the innocence or malignancy of the growths had to be determined by their clinical behaviour. It therefore appears that in a certain percentage of cases the histological character of a new growth is no reliable index to its malignancy or the reverse. This is especially emphasised in some of the cases now described as the specimens examined were typical and well defined. The distinction between granulation tissue and certain round-celled sarcomata is sometimes so extremely slight as to amount practically to nothing; so much is this so, indeed, that it is conceivable that the one may be confused with the other even by expert observers, as is shown, for example, by the following case.

CASE 18.—A girl, aged thirteen years, was admitted into St. George's Hospital under my care with some deformity of the humerus just below the surgical neck caused (it was stated) by the bone having been fractured in the same place three times during the previous year by comparatively trivial injuries, a very unusual sequence of events in such a subject who, beyond being rather delicate in appearance, seemed healthy, showing no sign of rickets or any other condition tending to brittleness of the bones. There was slight angular deformity at the spot alluded to and apparently a very large *amount of callus*. The union appeared to be good. A skiagram was obtained and the mass then appeared to be of the nature of a growth rather than callus. An exploratory operation was therefore performed and the mass was found to consist [illegible]in shell of bone containing a quantity of dark fluid and lined by a vascular jelly-like material of rather firmer consistence than blood-clot which was readily scraped away from the bony cavity which it lined. The cavity extended so near the *shoulder-joint that* any resection of the affected portion of the bone seemed inadvisable. As the contents of the cavity presented in aspect, consistence, &c., all the characteristics of malignancy amputation at the shoulder-joint was performed after consultation with one of my colleagues who was present. The microscopical examination of the material removed showed granulation tissue only; it was therefore quite clear that if this evidence was to be relied upon we had done this child a grievous harm in removing the limb. *To any one, however, who had seen the growth in situ* no possible doubt could have presented itself as to its malignancy, and in spite of the microscope revealing the characteristics only of an innocent tumour I am sure our proceeding was right. This belief was to some extent supported by the condition of the child when last seen. Her complexion had assumed a curiously wax-like appearance, the veins about the left upper chest and over the shoulder were much dilated and there was a suggestive area of dulness behind the clavicle. The left side of the chest moved rather less freely than the right, but that of course may possibly have been due to the loss of the use of certain muscles in consequence of the amputation.

The only tumours entirely disappearing spontaneously which have come under my observation have apparently been sarcomatous. I have never seen complete disappearance in a case of undoubted carcinoma, the nearest approach to it being that described in Case 9. As to the causes which lead to the occasional spontaneous disappearance of the sarcomata it is idle at present to speculate, but it certainly seems that actual interference with the integrity of the growth does in some way tend to its disappearance. It can, for instance, be hardly conceivable that the tumour of the testicle described in Case 4 would have disappeared if the exploratory puncture had not been made; the subsidence of the tumour commencing immediately upon the puncture is strong circumstantial evidence in this direction. Moreover, unless my recollection *misleads* me, I fancy that in the cases in which sarcomatous tumours have been treated by ligaturing the main blood-vessels supplying them the most striking results have followed when the structure of the growth itself has been laid open in the process of finding the vessels. It is a matter of much interest in connexion with this part of the subject that, so *far as* I know, no sarcoma on the surface of the body has disappeared spontaneously after incision or rupture of its structure; the cases of spontaneous disappearance seem to be limited to the disease when occurring inside a closed cavity like that of the abdomen or tunica vaginalis.

With regard to the cases of quiet carcinoma in *the condition* of negative malignancy, they are, I fancy, judging from personal experience more common than one would be led to expect from the literature of the subject. I have watched several of such cases occurring in the breast carefully over considerable periods and, assuming for the moment that the removal of carcinoma by *operation* (speaking generally) is a proper treatment, I believe that the best interests of the patient in cases like these are met by avoiding operation. It is true that it has been stated that if these quiet tumours are left untouched secondary visceral deposits, &c., are more liable to occur, but of this statement I am unacquainted with any proof and certainly the removal of these growths does not always obviate the tendency to subsequent developments, for I well recollect a patient being brought to St. *George's* Hospital with malignant disease of the vertebral column from whom Mr. Henry Lee had removed a "stony cancer" of the breast, ten years previously, the site of the operation being perfectly free from disease. Not only does the prospect of an operation often depress the patient and diminish the ordinary constitutional power of resistance, but the handling of the growth in the process of removal is prone to express the cancer juice (I use the term not of course in a scientific sense but because it conveys a very definite meaning), with the possible result of a direct local inoculation. In addition there is, so far as I am aware, no certain evidence to show that in cases of this kind, at all events in the breast, where they most commonly occur, life is prolonged or made in any way more comfortable by the removal of the disease.

The truth is that the proper estimation of the real value of the removal or other treatment in carcinoma is an enormously difficult matter. What, for instance, could have been better evidence of the successful result of oöphorectomy, supposing that treatment had been adopted, than the behaviour of Case 9? Moreover, in certain cases, especially those of the negative kind, the fact that recurrence does not take place for many years affords in reality no strong grounds for argument in favour of removal, as it is known that some of these tumours remain harmless for years when entirely left alone. I must here confess to being one of those who think that the operative treatment of carcinoma is carried to excess at the present time and, in my opinion, much more evidence than we now have at our disposal is required to prove that great benefit is derivable by operation in many of the cases treated. Moreover I think that in the case of the mamma which for surgical purposes provides so many cases of cancer the actual mortality of the disease has been to some extent over rated, as the bulk of the statistics dealing with the subject merely show the average length of life which follows after the discovery of the disease or upon its removal by operation in those who die from the disease, little or no account being taken of cases in which although cancer may exist the death of the patient is due to causes independent of it, the patients, in fact, dying with the disease but not from it. Of this class of cases I could give several instances in my own experience; in one the condition was only discovered after death, the patient having either been unconscious of its existence or having been successful in concealing it. In another case a patient who died from other causes had a shrunken painless carcinoma of the breast which she had succeeded in concealing for many years.

The cases of tumour histologically innocent at their commencement subsequently pursuing a malignant course are interesting and again show the occasional unreliability as an aid to prognosis of the results of microscopical examination. In the cases related there was no question of the failure in this respect being due to the provision of inadequate "specimens"; in one case the whole growth was submitted and in the others gross pieces taken from the centre of the tumours were provided. In cases like those illustrating the effect of mental concentration upon a part I am strongly of opinion that the increase in the growth of innocent tumours or the development of malignant disease may sometimes be dependent upon the mental attitude of the patient towards the affected spot. In 2 cases of what I have called negative malignancy I have seen tumours which had remained quite unchanged until the patients, previously ignorant of the probable nature of their complaint, unhappily had the suggestion made that the disease might be "cancer." Mental concentration was the result in each case and rapid increase followed.

I am further as sure as it is possible to be in the circumstances that recurrence of malignant disease after removal is not only more certain but more rapid in nervous, susceptible people than in those who are placid and dread less the second on coming of the disease. In using the term "nervous" here I do not intend it to be identical with "hysterical" in meaning, for it is my impression, without being able to adduce actual statistics to support it, that as a class hysterical subjects are less prone to malignant disease than those who do not belong to that type. By the term "nervous" I mean a certain class of sensitive, impressionable, and often very timid subjects who must be familiar to all practitioners, and it is in these subjects that the effects of mental concentration in the relation now being discussed are seen. Of the difference of the rate of growth in apathetic subjects as compared with that in nervous subjects it would be easy to give examples if time permitted. Case 9 already described is a sufficient illustration of the progress of a carcinoma in an apathetic person. The relatively slow growth and recurrence in some old people as compared with the rapid progress in the young is, I have little doubt, to some extent at all events although of course not entirely, accounted for by the blunted perceptions of the older subjects. Out of this matter a practical question arises. If I am in any sense right in my contention that the increase or development of new growths may in some degree be subject to mental influence what is the proper attitude of the surgeon towards the patient with respect to divulging the actual nature of the disease when it is malignant? On this point there is, I suppose, certain to be some difference of opinion since it is the custom of some surgeons at once to inform the patient of the nature of the disease if certain, or of its suspicious aspect if doubtful, without regard to individual peculiarity or susceptibility, and there can be no doubt that in the strictly abstract moral sense this attitude is from the point of view of the surgeon correct. It is, however, in my judgment certain that in some sensitive dispositions a direct opinion of this kind which is tantamount to a sentence of death may be followed by rapid increase and dissemination of the disease, and I am firm in my conviction that the suggestion sometimes made with regard to the possibility of an innocent growth becoming malignant is in such subjects a direct incentive to the increase of the growth and possibly to the change from innocence to malignancy. It is therefore, I submit, clear that no routine practice should be adopted in this matter but the attitude of the surgeon should, I think, be guided as much by the disposition of the patient as by the apparent nature of the growth. Indeed, in certain individuals, under some circumstances it is, I conceive, justifiable to conceal the nature of the disease, if possible, by deliberate deception, provided that the responsible friends or relatives are made aware of the exact condition of affairs. This question is one of extreme difficulty and requires more discrimination and tact on the part of the surgeon than any ethical question of a similar kind with which I am acquainted.

CONCLUSIONS.

A careful study of a considerable number of cases of which those just described in detail must be taken merely as characteristic examples and not as an entire experience leads me to the following conclusions:—1. That certain tumours although undoubtedly malignant in structure pursue an innocent course and disappear spontaneously. 2. That certain tumours malignant in structure become quiescent, assuming a condition of negative malignancy. 3. That some tumours originally innocent in type pursue a course of extreme malignancy. 4 That microscopical examination in a certain percentage of cases is powerless to determine whether a growth will prove malignant or innocent in its course. 5. That the clinical behaviour of new growths is often a better test of malignancy than microscopical examination. 6. That mental concentration on the part of the patient upon the site of the disease is a distinct factor in stimulating the growth of innocent tumours and in the production of malignant disease in certain susceptible subjects. 7. That in nervous subjects of the type described recurrence of malignant disease after operation is more certain and its growth more rapid than in persons of a placid or apathetic disposition. 8 That evidence is wanting to show that operation in cancerous tumours of the breast which have assumed the condition of negative malignancy is as a rule necessary or advantageous. 9. That although the practice of candidly announcing to patients suffering from malignant disease the nature of their complaint is, speaking generally, moral and salutary it may be modified with advantage in patients of the nervous type already indicated.

In expressing these views I am aware that some of them may be directly opposed to those held by many surgeons. They are, however, deliberately advanced after due consideration. The time at my disposal is only sufficient to enable me to touch the fringe of a subject of considerable magnitude which those who think it worthy of investigation will, I think, find of unusual interest.

BRITISH PHARMACEUTICAL SOCIETY.—The annual meeting of the British Pharmaceutical Society will be held in Plymouth next July. The society visited Plymouth twenty-two years ago and the local committee are already taking steps to ensure the success of the meeting.

"collaterals" by Ramon y Cajal, the relations of which are imperfectly known. They have been seen to end by a T-like division and ultimate branching.

The definite and extended discernment of another fact deepens the importance and application of that just described. Thirty years ago[9] Max Schultze discovered and depicted the fact that the axis-cylinder is compound and not simple, that it consists of a large number of fibrils—"primitive fibrils," he termed them. He pointed out that they could be traced throughout the fibre, separated by a finely granular substance. They could be well seen where the axis-cylinder widens in joining the nerve-cell—that is, where the cell narrows into its chief process. Others could not see the significant striation, among them Ranvier, whose work dominated science throughout the next fifteen years, and the fact was practically ignored. The axis-cylinder was regarded as simple and integral, until recent methods have enabled the clear establishment of the correctness of Max Schultze's observations. The number of fibrils which constitute an axis-cylinder is considerable. Obersteiner has found that there are about fifty in an axis-cylinder of the sciatic nerve of the frog.[10] These fibrils consist of a conducting substance, the "hyaloplasm" of Leydig and Nansen (so termed from its greater translucency in hardened tissue). This is isolated by a slightly granular material, distinguishable chiefly by its difference of aspect and staining after the changes produced by hardening agents. It has been termed the "spongioplasm"—"plasm" because it also has a soft consistence, "spongio" because it is said to form trabeculæ which constitute the chief element in the ground substance or matrix of the "spongy" grey substance[11] in which the cells lie and their processes branch. From this compound constitution of the axis we must infer that its terminal [illegible] branches is merely the separation of these division [illegible] and at last into single fibrils—fibrils, first into gr[illegible] so at the periphery and in the "primitive fibrils." It [illegible] be termed "axites," grey matter. The final twigs [illegible] The short branch- if a special designation seems needed.[12] [illegible] fibrils, processes have been found to consist of [illegible] of is true also of those supposed to be extensions [illegible] [illegible] of the cell and therefore called "proto- [illegible]cesses." This name should be given up with the [illegible] attached to it. The opinion that their function convey nutritive material to the cell-body was, indeed, never more than an hypothesis, resting on no real foundation.[13]

With the recognition of the fibrillary constitution of the axon and dendrons has been associated an equally important recognition of the fact (most clearly depicted by Max Schultze[14]) that their fibrils pass through the body of the nerve-cell without interruption. Those of the axon diverge to pass to the several dendrons, but those of the latter do not pass all to the axon. Some pass directly to other dendrons, so that in such there must be conduction from the cell as well as towards it.[15] Moreover, both Ramon y Cajal and Kölliker have observed in certain cells of the cerebellum all the fibrils of an axis-cylinder pass directly to a dendron, scarcely entering the body of the cell. Twigs from such processes of small cells, especially in the invertebrata, have been said to join the elements of the neuroglia.[16] The fact is in harmony with the origin of both from the same embryonal tissue. The differentiation of the nerve elements from this may leave some blending of structure. It must be remembered that there is much uncertainty regarding the nature of many of the smaller cells, and it is conceivable that some are nervous and some neuroglial and that there may not be always actual separation of their connexions.

An essential difference between the axon and the dendrons cannot as yet be established. Branching does not differentiate them, for the axon also branches after a long course. Nor does either multiplicity or length. The cells of the posterior ganglia of the cord have but one axon and one dendron, united for a short distance as the single process of the "unipolar" cell. These two processes are of nearly equal length in the case of those cells that give rise to the fibres of the posterior median column; these, reaching the cord by the posterior roots, ascend to the level of the medulla, while the other division of this cell-process probably comes from a muscle as far away. We see also in this instance the absence of any real distinction from the direction of conduction. Although the axons of the motor cells conduct from these, so also must some of those dendrons to which fibrils pass from others. Moreover, in the case of the posterior root-fibres, which go to the local grey matter the long fibre from the periphery conducts towards the cell; the shorter fibre, which soon branches in grey substance, conducts from it. Opinions may differ as to which should be regarded as axon and which as dendron, but analogy suggests that the latter should be that which soon ends in the grey substance. Yet it is difficult to avoid regarding each fibre of the cells related to the posterior median column as an axon. There is no reason for regarding either a dendron or an axon as an essential element of a cell. Yet the distinction is necessary, and the general application of the names is justified by the common difference between the one medullated process which passes out of the grey matter and the other numerous processes which are not medullated and soon divide within the grey substance.

The extent to which the physiology of the nervous system is inferred from its minute anatomy is illustrated by the revolution in our conceptions produced by the discovery of the discontinuity of its elements, the fibrillary constitution of the conducting structures, and the course of the fibrils. These, passing through the nerve-cells without interruption, can merely [illegible] through the cell-body as they do elsewhere in [illegible] course. With this fact disappears the [illegible]mple, apparently so adequate and reasonable from its superficial analogies—the idea that the nerve-cells are the seat of the production of nerve-impulses, that in them "nerve force" is generated from the latent energy stored in the nutritional compounds which have entered into their constitution. But we cannot have such generation where the fibrils are continuous. For it we must look to their extremities, formerly supposed to be in the cell-body, now perceived to be in the "spongy grey substance." The process must be where the continuous fibrils begin in the centre, as it is in the skin and other parts of the periphery, in the case of fibrils that conduct thence. As all the nerve-impulses that reach the centres, through which external influences act and the environment is perceived, originate in the minutely separate nerve material at the extremity of the afferent fibrils, so all the outgoing impulses and those which pass from one part of the centres to another originate in their special form at the analogous extremities of the fibrils in the grey substance. We must conceive these impulses arising in the extremities of the "cellulipetal" dendrites (to use the somewhat cumbersome term of von Kölliker) being excited in some way by the stimulus of the impulses which reach the contiguous extremities of other "cellulifugal" fibrils, dendrites, or branches of the axon of a distant cell. The incoming impulses may excite those that go out, as impulses are excited at the periphery by other forms of energy; or there may be a process of conduction through the intervening ground-substance—the matrix in which the cells lie and the dendrites end. For the increase in the amount of nerve energy which often takes place there must be more than conduction, its production must be "excited" by that which is conducted. We can conceive such excitation without continuity, especially when we consider that the stimulation of muscular protoplasm is by the impulses in nerves which terminate on the fibres, and not in continuity with the contractile substance—indeed, separated from it by a structure apparently quite different in its simpler nature.

If this conception of the origin of the impulses in the terminations of the fibrils seems less easy than their origin in the more massive nerve-cells we must remember how multiplicity neutralises minuteness. Indeed, the minuteness of the conducting fibrils almost involves a multiplicity of minute sources of nerve impulses—which must, moreover, be far from minute in comparison with the molecules from the latent energy of which the impulses proceed. All modern discoveries prepare us for finding every mass to be an aggregation and each perceptible quantity of energy to be made up of minute constituents, every one of which is definite both in its separate character and in its contribution to the effect of the whole The finely divided nerve-substance will constitute a total source of energy as adequate in extent as a nerve cell, with a more obvious facility for the renewal of the molecules lost in functional action and far greater opportunity for varying relation to the structures from which the impulses are received

[9] In 1868; see Stricker's Histology (New Sydenham Society's Translations). The observations were confirmed by Babuchin in 1868 and 1869.

[10] Personal communication.

[11] Apathy, Biologisches Centralblatt, 1889. The term "spongy grey substance" was before in use on account of the sponge-like interlacement of the cell-processes. The conception attached to it has thus become somewhat confused.

[12] Especially since one writer has termed them neurites, which would be confusing unless the axis-process were termed the "neuron," as it certainly will not be. The only proper use of this word (neurites or neuronites) would be for the terminal twigs in general.

[13] That these dividing branches, long and not obviously permeable, should be the channels by which the cell receives that which could pass directly through its walls was simply a positive inference from the negative fact that no other function was obvious. That we must cease to consider these processes "protoplasmic" and nutritional was insisted on in 1890 by Rabl Ruckhardt (Neurologisches Centralblatt).

[16] Among others by Ladowsky: Verhandlungen des Medicinischen Congress, Berlin, 1890, Band ii., p. 92.

What then is the function of the nerve cell? The one certain fact established by evidence that is secure is that on *it depends the life of the nerve fibres—the vitality of all the* processes equally that of the dendrons and of the axon The evidence of this the immediate degeneration of any separated part is well known It is less conspicuous in the case of the dendrons but sufficiently certain How the influence is exerted we can only surmise The nucleus of every cell is its life centre and in some way the nutrition of the protoplasm is determined by it The cell body has a complex structure dimly perceptible by the help of reagents, at present beyond our practical comprehension One distinct fact, however, is that the protoplasm of the cell extending into the narrowing axon thins away between the outer sheath and the white substance, becoming unrecognisable until one of the many nuclei is reached Each of these is surrounded by like protoplasm also thinning off along the fibre until invisible It is certain also that if the cell body and nucleus are destroyed or the fibre separated the process of degeneration begins by changes in these nuclei They seem to be concerned in carrying on the influence of the distant cell, and it is not easy to conceive any other path for this influence than a thin layer of protoplasm within the sheath, continuous from nucleus to nucleus, vitally influenced by these and conveying by its own nutritional state, that of the cell *A space in this position is rendered* visible by reagents which make the contents of the sheath shrink Indeed coagulated material in small quantity can be seen within it [17] This has been regarded as evidence of the presence during life of such a space as is here assumed to contain connecting protoplasm

Many facts previously obscure became more intelligible in the light of the new discoveries The knowledge that the cell governs the nutrition of the fibre and the belief that from it proceeded the nerve impulses involved a correspondence in the direction of nutritional influence and of conduction, and it was found, in fact, that conduction and degeneration were in the same direction as a rule, but only "as a rule" It was untrue of the sensory nerves These coming from the cells of the ganglia on the posterior spinal roots degenerate downwards but they conduct upwards—an anomaly which had to be simply ignored The fact is now seen to be in harmony with others The arrest of secondary degeneration in the grey matter, the fact that the degeneration of the fibre which enters the grey matter never passes on to the next nerve cell, through which conducted impulses *must pass, was* mysterious when they were believed to be in continuity The discontinuity explains it at once The degeneration is limited to the single neuron The division of the axis cylinder at its terminal ramification whether that of the sensory nerve in the skin or of the motor nerve in the muscle was scarcely intelligible when the axis cylinder was regarded as a single conducting path, it is so when we perceive that the apparent division is simply the separation of its constituent fibrils each a distinct conducting path This fact is moreover, especially important in relation to the minute localisation of the various forms of sensation in the skin The sensory nerve fibres themselves are not numerous enough to subserve this localisation, which could not result from the division of an axis cylinder that conducted as a whole The fact that the special form of energy termed a "nerve impulse" may arise in a fibre in its course under the action of a stimulus that the capacity of the fibres is not limited to 'conduction' is less surprising if we conceive all such impulses as produced at their extremities

While old difficulties thus disappear and many facts become more readily intelligible so great a change of our conceptions involves new difficulties Not only are the structures concerned most minute, but their discernment depends on the use of reagents which reveal them by developing differences in aspect due to chemical changes; new physical characters have been produced by other agents of the same nature There seems but little original difference in consistence between the material that constitutes the conducting axis of the "primitive fibrils" and that of the separating substance Both are apparently almost diffluent during life, and are indistinguishable physically until their difference in constitution is revealed by the action on them first of the chemical agents that harden and then of those that stain [18] Both processes involve molecular chemical changes which multiply initial differences and leave the actual amount of these more obscure than we are apt to think

The conducting element of the fibrils the 'hyaloplasm" or "kinetoplasm," is said to be more diffluent than the separating "spongioplasm" but the difference may be chiefly due to the hardening agents used Continuous within the tubules and through the cell body into the dendrons it has been said that beyond these it is also continuous with similar material in the matrix of the spongy substance Into this also the spongioplasm is said to pass and form a trabecular structure The fact that the fibrils as stained by Golgi's method, apparently end must indicate that these elements, if continuous with those of the matrix are different in nature in some degree The difference may be much exaggerated by reagents, and yet sufficient to constitute the functional discontinuity which is generally assumed to be as structurally absolute as it appears in the sections Until we know what the structure of the matrix is we can scarcely conjecture the nature of the process that occurs in it between the dendrites 'Conduction' may have been too readily regarded as impossible and it is not clear that actual conduction of nerve impulses is incompatible with the augmentation which we include under the term "excitation" An increase must occur when for instance, in many reflex actions the afferent impulse that reaches the spinal cord is minute in proportion to that which leaves the centre We *seem thus to have a* process of stimulation comparable to that in the cutaneous nerves (themselves apparently analogous to dendrites) under the influence of some other form of energy from the outside In this connexion it is especially noteworthy that many dendrites terminate in knob like enlargements suggesting receptive functions We do not know the nature of a nerve impulse We must, however, assume that it is energy in some form of motion released from that previously latent in the nerve substance, apparently the "kinetoplasm" or 'hyaloplasm' Chemical change occurs by which simple compounds are formed as in all similar processes and the simplest conception is that the process is like that in a train of explosive material modified, restricted but perhaps accelerated by the influence of life [19] The motion of a touch which acts upon the nerve endings in the skin reaches them by passing through the skin as the simplest form of motion, so also pass the special forms of wave motion that constitute electricity and heat A differentiation of the nerve tissue in *the ending* seems to enable their molecules to receive one special form of motion most readily Hence our "special senses" The manner in which the equilibrium of the nerve-substance is disturbed in each doubtless differs much but it is instructive to note in connexion with the theory of the nerve impulse just suggested that the wave motion of light seems first to induce recognisable chemical changes in material of unknown nature

The application of these new conceptions to disease we must postpone to another occasion

[17] Schiefferdecker: Archiv fur Mikroskopische Anatomie Band xxx 1837

[18] In connexion with the fact that molecular differences between substances apparently the same even when examined with the utmost minuteness may be revealed by staining the facts of the colour photography of Cassagne may be noted The waves of light which differ only in rapidity and length but by this excite different elements of the retina reduce a special silver salt in the gelatin film in different degree. *Extremely slight* as must be the resulting difference in the molecules which is produced it apparently suffices, augmented by some additional chemical process, to make each of them retain some stains and not others

[19] This view has been developed at length in the writer's "Dynamics of Life" (London Churchill 1894) but was clearly stated by Herbert Spencer Elements of Biology, vol. i 1864.

NEUROLOGICAL FRAGMENTS.

BY J. HUGHLINGS JACKSON, M.D. ST. AND., F.R.S.,
CONSULTING PHYSICIAN TO THE LONDON HOSPITAL AND PHYSICIAN TO THE HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

(Continued from THE LANCET *of Jan. 2nd, 1897.)*

No. XVIII.

ON ASPHYXIA IN SLIGHT EPILEPTIC PAROXYSMS.—ON THE SYMPTOMATOLOGY OF SLIGHT EPILEPTIC FITS SUPPOSED TO DEPEND ON DISCHARGE-LESIONS OF THE UNCINATE GYRUS.

IN severe fits of epilepsy there is arrest of respiration from spasmodic fixation of the chest and perhaps there is spasm of the diaphragm also. In some slight epileptic attacks, *les petits maux*, the patient "turns blue" or "purple"; he may become livid, a "dark pale," to use the expression of the friend of a patient of mine. I have until recently thought that asphyxia in slight fits is owing to spasmodic fixation of the chest and have indeed supposed that some slight fits with asphyxia and without true convulsion of the arms were respiratory (bulbar) fits owing to discharges beginning in the respiratory centre. Certain researches by Mr. W. G. Spencer ("The Effect Produced *upon Respiration* by Faradic Excitation of the Cerebrum in the Monkey, Dog, Cat, and Rabbit"),[1] make me think *that another* explanation of asphyxia in slight epileptic fits or at least in a certain group of them, *is more likely. In* this note I only refer to that part of Mr. W. G. Spencer's researches which deals with arrest *of respiration.* On p. 629 *op. cit.* Mr. W. G. Spencer writes: "It has, therefore, been shown that the respiration can be *slowed and arrested* by excitation of a certain spot and a limited area around it. This spot is situated in all the animals *examined to the outer* side of the olfactory tract just in front of the junction of the tract with the uncinate. And this *arrest can be constantly* obtained and the experiment repeated again and again under certain conditions." On p. 628 Mr. W. G. Spencer *writes:* "The arrest in the monkey was nearly always in expiration, but only rarely was any active *expiration seen.*"[2]

I presume that the arrest is by great *cortical inhibition of* the respiratory (medulla) centre; a superior centre of the lowest level.[3]

I have several times[4] drawn attention to what I will now call a group of cases of epilepsy—*cases in which there is at* the onset of the paroxysms a crude sensation of smell or of taste or in which there are movements of chewing, smacking of the *lips*, and *sometimes spitting*, &c. These movements are the indirect, the "reflex," consequences of an epileptic discharge *of gustatory elements* of the cortex. In some cases of this group there is a warning by what is known as the epigastric *sensation*; *this sometimes* occurs along with one of the other crude sensations or with the chewing, &c., movements. The representation of smell and taste is, according to Ferrier, in the uncinate gyrus; excitation of this gyrus in the animals he experimented on produces, he found, "reflex" movements analogous to those just mentioned as occurring at the onset of certain slight epileptic fits in the human subject.[5] Different varieties of this group of cases depend, I suppose, on discharge lesions of different parts of the uncinate gyrus or of parts of convolutions in its close neighbourhood. As will have been inferred it is supposed that in this cortical region are the physical bases of some systemic sensations—to speak very roughly of those systemic sensations especially appertaining to the digestive system.

There is very often the Dreamy State in cases of this group of epileptic fits—the Uncinate Group.

I have had very few opportunities of watching patients in slight paroxysms of epilepsy with regard to degrees of asphyxia. In slight attacks of the group of cases just spoken of there is sometimes "turning blue," as the friends may say. Here comes, I submit, the importance of that part of Mr. W. G. Spencer's research which I have quoted; his "arrest centre" is very near to the uncinate gyrus. So that if an epileptic discharge does begin in some part of that gyrus it may spread to and may soon reach the "arrest centre": I say "may spread to and may soon reach" because no doubt the degree of spreading and range attained by an epileptic discharge depends on the initial discharge—on the degree of fulmination of the discharge-lesion (quantity of energy liberated and rate of liberation). I suggest particular inquiry and careful observation regarding degrees of asphyxia in slight paroxysms of the group of cases of epilepsy I am dealing with; the colour of the face (especially of the lips), the state of the chest walls and abdomen, and the attitude of these parts, inspiratory or expiratory. Besides this, I ask a question which is, I think, of great importance: Can a considerable degree of asphyxia occur in a slight fit without spasm, real convulsion, I mean tonic or clonic, of the arms? (I am not meaning that slight and yet true spasm of the hand (fingers) may not be present when the rest of the arm is not convulsed.) It is to be urged that on arrested respiration in slight fits there may be writhing movements of the arms, and no convulsion properly so-called of them. The writhing movements are presumably an indirect consequence of (the physical condition for) suffocation.

The following case will serve to illustrate what I have just said. A man, F. F——, aged fifty-two years, had a "funny feeling" which was not true vertigo; of this feeling he said, "I can't tell what it is." I could not be sure it was the dreamy state; very likely it was not, at least not a definite one as in this patient's case I asked leading questions on the matter. His wife knew when his attacks were coming on by a noise he made; she smacked her lips as if tasting to let me know what the noise was. When this noise stopped the patient (his lips) "turned blue"; his eyes were half closed. His arms dropped *soft*, not *stiff*. When he came round he "*drew a long breath*" and began to breathe easily and then seemed "dazed and muddled" and "asked unlikely questions." In this case there was some kind of abnormal affection of taste *after* the attack; he told me that he had after the attacks a peculiar taste in his mouth, "everything nasty," everything tasted alike; he had complained of this to his wife.

Smacking movements of the lips, nasty taste, dreamy state, if there was one, and "turning blue" may seem at first glance to have no sort of relation to one another. I submit that they have an association in the sense that there is one discharge-lesion of some cells of the uncinate gyrus and that there is spreading of the discharge from this focus. I believe, too, that the dreamy state (which as I have said often occurs in this group of fits although perhaps not in the case of F. F—— just narrated) is a consequence, a very indirect consequence, of a discharge-lesion so seated. On looking up my notes of this case I was much interested in the *observation* of the patient's wife that in the paroxysms his arms were soft, not stiff; it seems that there was asphyxia without any convulsion of these limbs. I will, however, refer to the case of a boy, ten years of age, recorded by Herpin in his valuable work on Epilepsy published in 1852 (p. 275), with regard to the arms in epileptic asphyxia and to several other matters of importance in the analysis of the symptomatology of epileptic fits.

Herpin says that the boy's parents included under the head of vertigo two varieties (I should use the term degrees) of incomplete fits (slight fits). There is no mention of a dreamy state; it is the kind of case in which I should expect there to be one. The boy had also severe attacks[6] which were always preceded by the incomplete attacks.

"At the beginning of the more severe seizures [the severer of the two degrees of incomplete attacks is meant], which happens like the other kind of fits, without any apparent cause, the child experiences a sensation which begins in the abdomen and the stomach and rises up to the neck; he then says, 'I am ill! I am ill!' *Then he starts chewing motions (champing)*[7] *and his mouth fills with water*, in spite of noisy efforts at deglutition. At the same time the contractured hands and forearms are flexed and subject to irregular movements (not tremors or jerks)[8] which tend to carry the open or closed hands towards the head; the face was immobile and distorted, at first pale, then livid or purple (*violette*); the eyes are haggard. Whether seated or standing at the onset of the attack the child does not fall, but is willing to be supported. In the later stage of his malady, happening to have a seizure in the street, he continued walking, at first alone but like a drunken man, afterwards with help. That the child did not fall is not the only sign from which one could conclude that he does not entirely lose consciousness: as saliva runs from his mouth towards the end of the fit, *he seizes a handkerchief which was offered him; and he tries to wipe his lips*, but his arms seemed unable to be under the control of his will.[9] Sometimes during the seizures he repels any service offered him; indeed, one day he even answered a question by a few words. After the convulsive state, which lasts from one to three minutes, he remains quite quiet for a moment and then is well again. Sometimes in the course of the attack there will be efforts at vomiting. To sum up, this variety consists of exclusively tonic convulsions restricted to the upper portion of the body with more or less complete preservation of the senses and intelligence.

[1] Transactions of the Royal Society, vol. clxxxv., 1894, B., pp. 609 to 657.

[2] By the latter part of the quotation is meant a degree of expiration in excess of the *normal*.

[3] THE LANCET, Feb. 23rd, 1895: On Superior and Subordinate Centres of the Lowest Level.

[4] Medical Times and Gazette, vol. i., 1879; Brain, July, 1880; July, 1888; and (with Dr. Beevor) Brain, October, 1889.

[5] I have had under my care a patient who had slight epileptic fits (he had severe attacks too) which began by his making such mouth movements as I have mentioned in the text; no crude sensation of taste was remembered by the patient on coming round from his seizures: there was the dreamy state. In this case Dr. Colman found a very small focus of softening in the left uncinate gyrus.

[6] "Attaques [illegible] dites."

"In the less severe variety [of the incomplete attacks] which very nearly resembles simple vertigo, there are general immobility, *champing*,[10] sounds of deglutition, sometimes there is slight lividity of the face, but no convulsion of the limbs."

My reason for citing this case is partly on account of the champing movements (with an epigastric sensation) and also because of Herpin's statement about the arms when the patient was purple—the "irregular" movements, his seizing the handkerchief and his inability to use it. I suggest that in this case the champing movements signified a discharge lesion of gustatory cells of the uncinate gyrus and that the discharge besides spreading to motor centres for those movements spread also to the arrest centre and thus caused, by inhibiting the respiratory (medulla) centre, the patient's face to become livid and purple. I submit that the irregular movements of the arms were, like those of champing, movements proper, vague movements, especially of the accessory muscles of respiration, consequent on a state of suffocation. However, I must not forget that Herpin spoke of them as being part of a tonic convulsion.

In future notes I shall speak of symptoms of the group mentioned in this note with comments and may reconsider the state of the arms in the asphyxia of slight epileptic fits.

SURGERY IN THE GRÆCO-TURKISH WAR.

BY FRANCIS C. ABBOTT, B.Sc., M.S. LOND., F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS TO THE EVELINA HOSPITAL; LATE CHIEF SURGEON TO THE "DAILY CHRONICLE" NATIONAL FUND FOR GREEK WOUNDED.

THE first part of this paper was in the hands of the Editors of THE LANCET before Christmas, 1897. Prolonged absence from work has delayed its publication; the results in more recent campaigns are therefore not alluded to.

Military Surgery at the Present Time.

The enormous surgical experience gained in some previous wars, with their vast numbers of men engaged and their long duration, may well make one pause before publishing a comparatively limited series of cases like my own. But war and surgery are changing sciences and in both there have been such great alterations since the last European war as to vitally alter the character of many of the problems with which the military surgeon has to deal. On the one hand the magazine rifle, throwing sheathed bullets of small calibre and high velocity for enormous ranges, has introduced a factor about which little is yet known, but which will certainly change the character of many of the wounds received in battle. It is only necessary to read the interesting chapters in which the most modern English text-book on military surgery[1] discusses the effects produced by the small bore bullet at different ranges and velocities to realise that as yet there is much to be learnt about them.

The chief experimentalists have differed widely in their results, mainly, I think, for two reasons. One is that the effects produced are not the same on the coagulated tissues of a cadaver as on the living, and the other and more important is that in so many experiments the charge has been diminished in place of increasing the range. This certainly obtains the same reduction of energy in the bullet but not the same effect, for some reason, on the tissues. In war where otherwise the experiments would be so perfect the results are vitiated, as a rule, by want of knowledge of the distance from which any particular bullet has been fired and by the fact that in many cases where the tissue damage is greatest the doubt occurs as to whether the bullet has not already struck something and so been altered in its shape before entering the body. In our cases where the bullet had completely traversed the body there was sometimes an additional doubt as to the calibre of the bullet. Some of the Turks were armed with the Mauser and the remainder with the Martini-Henry rifle. Wherever possible this point is noted but in many cases it had to remain uncertain.

On the other or surgical side there has been an equally great improvement in our antiseptic methods, especially perhaps in the way of simplicity and ease of attainment, making their successful application to military surgery not only possible but comparatively certain. In this connexion it was against us that many of the cases had not received any first aid. Some of the wounds were covered with an antiseptic pad, others had been bound up by the men themselves, but many were quite uncovered. On the other hand they had not been tampered with in unfavourable surroundings and they were not brought down in soiled ambulance waggons but all on horse or foot. The atmosphere was pure and the last part of the journey was performed in steamers not previously used for this purpose and which, though dirty, must have been fairly free from pathogenic organisms. The discovery of the Roentgen rays and their use for the detection of hidden bullets has also put a new weapon into the hands of the military surgeon.

The Conditions and Equipment of the Two Temporary Hospitals Employed

My experience was gained in two temporary hospitals in which 153 cases in all were treated to a termination, and of these careful notes were taken. For the treatment adopted I was as far as possible responsible, though owing to the distance which separated the hospitals and heavy administrative duties much of the actual management of cases fell to my colleagues, Dr. H. J. Davis, Mr. R. Fox Symons, Mr. H. Moffat, and Mr. S. Osborn, to whose careful work I am much indebted. To Mr. H. Moffat at the Piræus fell practically the sole charge and initiative in many bad cases and excellent results he obtained. We treated at Chalcis a large number of other bullet-wound cases temporarily, but for want of room passed them on to Athens. These and many others which I saw in the various temporary and permanent hospitals by the courtesy of the Greek and foreign surgeons, no doubt helped to form my opinions.

As military surgery is mainly ordinary surgery under difficulties a word must be said as to surroundings and equipment. Our hospitals were placed in a villa at Phalerum (kindly lent us by Her Majesty the Queen of Greece) and a large one-storeyed pavilion building at Chalcis. Both had been crowded with refugees and were very dirty when we took them over. Disinfection was carried out by burning sulphur, by double lime-washing the walls, and by the employment of much carbolic acid and soap-and-water. We apparently got rid of the microbes but were not so successful with macroscopic foes. The house at Phalerum was connected with the drainage system—a doubtful advantage as we did not know in what way. Chalcis, on the other island, has no sanitary arrangements, and as it had 15,000 refugees quartered on an original 9000 inhabitants disease was very rife. The kitchen and offices were over a large cesspool, luckily connected only with our own building. It was too dangerous to make any great change, so all we could do was to partially close it and have frequent supplies of antiseptics thrown into the remainder which we were obliged to continue to use. Typhoid fever and small-pox were both very prevalent but we had no cases among the staff or patients except those which came down from the front with the former disease. For filtering water we used throughout Berkefeld filters, relying on their efficacy for both surgical and drinking purposes. The form adopted was a hand-pump supported on a stem ending in a stirrup for the foot. The machine could be taken to pieces, was very portable, and it was possible to pump half a gallon of filtered water a minute. I had no means of testing this water bacteriologically, but no case of the fearfully-prevalent typhoid fever arose in either place. I also used this water as sterile in surgery, because from the smallness of the open charcoal stoves it was impossible to boil sufficient, and as far as I know I used it without any bad result.

---

[7] "Il se met à mâchiller."

[8] "Sans tremblements ni secousses."

[9] "Mais ses bras ne semblaient pas obéir régulièrement à sa volonté."

[10] "Mâchillement" (this word is the only one italicised in the original except that of the patient's exclamation "J'ai mal"; the other italics are mine)

[1] Wounds in War, by Professor Stevenson.

The hospital near Athens was furnished with beds and other fittings locally bought. The arrangements at Chalcis were more primitive. The beds were planks on trestles and the mattresses, for want of hay or straw, were stuffed with cotton-waste. The rooms, however, were large and airy, the largest ward containing 22, and the smallest 11, beds. Owing to overweight we left behind in England to follow by steamer all such nursing adjuncts as urinals, bed-pans, porringers, &c. I should advise anyone about to undertake similar work to sacrifice almost anything rather than these, as other things can be more easily extemporised, while nothing is more necessary in the treatment of bad cases. The patients in both hospitals were tended by English nurses assisted by Greek orderlies. The *Daily Chronicle* had generously given me a free hand as to equipment and we had a full supply of modern instruments and dressings.

On instruments I have little to say. Nearly all operations are of a cleansing and trimming character and require ordinary tools. We much preferred the new "Egyptian Army Pattern" bullet-forceps to any others. Those with sharp-toothed ends we found both difficult and dangerous to work at the end of a long sinus which with the new bullets is even narrower than formerly. I much prefer a long periosteal elevator with slightly curved end to any forceps whenever possible. All difficult bullets should be cut down on by a fresh incision and the track ignored. There is no hurry about removal and if the sinus is healed asepsis is all the more certain. We had no opportunity of using Murphy's button or other rapid means of intestinal suture, as the two cases of perforation of the gut were neither suitable. All instruments were sterilized by boiling before and after use. The chief dressings were cyanide gauze and Robinson's tissue and the antiseptic perchloride of mercury in tabloids or soloid cartridges for making larger quantities of solution. We of course used a good deal of carbolic acid, but found its bulk, the heat needed, and the time spent in preparing a solution distinct disadvantages. Creolin proved an excellent lotion for cleansing long suppurating bullet sinuses. We did not chance to need saline infusion, but the simple apparatus required should always be at hand, as many of the most favourable cases for its use must occur after hæmorrhage in bullet wounds. We had with us anti-tetanic serum, but no case of tetanus arose. Several cases of the disease occurred during the war but it was not common.

THE ROENTGEN RAYS (WITH MR. R. FOX SYMONS, BY WHOM MOST OF THE SKIAGRAMS WERE TAKEN).

The great field of future usefulness for the x rays in war is obvious; their limitations can only be told by experience. We were fortunate in having with us a powerful coil and all the other essentials for x ray work. This was the only apparatus of the kind in Greece and we therefore received cases from other surgeons to supplement our own and were in the position to gain a larger experience of the use of the rays in bullet wound cases than had yet fallen to other surgeons. The equipment was kindly chosen by Dr Barry Blacker and furnished by Messrs. Miller and Woods. The only difficulty we had with the battery was the melting of the pitch of the partitions between the cells owing to the heat. The coil gave a nominal 10 in. spark. We only used three Crookes's tubes throughout, but, of course, in such circumstances as ours it is very advisable to have a good reserve. We had a large screen of platino cyanide of barium which proved the means of saving much time and is probably even more necessary in war than in work elsewhere. The troublesome question of depth is so easily approximately solved by its aid. The only disadvantage is that we have not permanent optical records of all the results.

The chief difficulties in the use of the rays in war as they presented themselves to us were—the great weight of the coil and secondary battery, the absolute necessity of having a source of electric supply near at hand to recharge the batteries, the fragility of Crookes's tubes and glass negatives, the danger of carrying strong sulphuric acid, the difficulty of sparing the space and of making an efficient dark room with good water-supply, and the time taken up by the work. Besides these there is the general delicacy and liability to derangement of the whole apparatus, as every x-ray photographer will understand, which makes the manipulations a great extra anxiety when one is already working at high pressure and short-handed in disadvantageous surroundings. A more amusing source of difficulty was the superstition of the natives. They undoubtedly looked on the whole affair as the work of 'ο Διαβολος. It made it difficult to take a skiagram when the subject was constantly crossing himself unless strictly watched. Some of these difficulties quoted above absolutely preclude the use of such an apparatus at the actual front. It would of course be possible to work with a less powerful coil and battery than we used, but such small machines will only give results with easy cases, as hands or forearms, and are of no use for working with the screen. But if one is ever to use the rays in the first rush and press of wounded after an engagement it is clear that it can only be by means of the screen. There is no time for anything else. And as to use the screen efficiently demands a big spark and a heavy coil the thing becomes an impossibility at the actual front. Fortunately it is not really necessary there and could very possibly do harm by stimulating the young surgeon to premature operations in bad surroundings.

In the great majority of the bullet wound cases which come in the bullet has already passed out. In a good proportion of the remainder it is easily felt under the skin and extracted. These alone should be dealt with at once. On the other hand, the skiagram should, if possible, be taken before the necessary cleaning and splinter removing operations performed at the advanced base or line of communication hospital. The bullet will, of course, often be found in these even without the help of the rays. Putting aside these cases it is quite a small minority in which the location of the bullet remains hidden. These are just the cases which can wait and are at first merely dressed, or which (as in lung cases) only develop serious signs later, and are the ones which in a week or two will be arriving at the base. Besides these there are those cases in which no bullet is thought to be present but which do not go on well. These also can be skiagraphed as they arrive at the base and the source of irritation, be it bullet or sequestrum, often discovered. Although Domoko was fought on May 17th we did not often feel the want of the rays before we had our apparatus fixed which was not till June.

We believe, then, that the x rays in future wars will be of the greatest use but *not* at the actual front. In a European war they will of course be readily obtainable at the base, but so much of the surgery must be done before the cases get down so far that they will be wanted further forward than this. In Europe it will nearly always be possible to find some town near the fighting line with electric installations and this will be the place to choose. In our English service this would probably be the site of the most advanced of the line of communication hospitals. In wild countries the difficulty of obtaining electricity will always be enormous and must be the chief determining factor. In such difficulties the plan used is worth remembering. Every modern man-of-war can furnish an abundant supply which will, of course, be given for this purpose with pleasure.[2]

In Greece the apparatus was fixed in a room at the hospital at Phalerum. This was practically an advanced base hospital. Chalcis was ten hours nearer the front but there was no possible source of electricity. Phalerum also was near enough to Athens for the Greek surgeons to bring us their cases. We obtained our electric supply from H.M.S. *Rodney* to whose officers we were much indebted for their willing help. We used no glass negatives, thus saving weight and having less chance of breakage. All the skiagrams were taken direct on to Eastman's positive paper and we would recommend this method to others in similar circumstances. In the only cupboard we could spare for a dark room we lacked that great essential a good water-supply, hence from insufficient washing some of the pictures have since considerably "fogged."

---

[2] Since the above was written Major Beevor, R.A.M.C., has successfully worked with a primary battery at the front in the Afridi campaign.

In addition to looking at all the cases in which we had reason to believe bullets or fragments of them were still in the tissues we took skiagrams of bullet fractures. These show plainly in what very various directions the lines of fracture may run from the point of impact. They vary from almost longitudinal to quite transverse. In some instances multiple fractures start from the bullet hole and in others the fracture commencing as one breaks up into several branches. One os calcis shows only a clean hole and another shows a true stellate fracture with the hole as centre. Fragments of bone in other cases have been driven into the surrounding tissues. Probably the unknown factor of range (and therefore velocity) would explain these differences. The absence of callus puzzled us at first, but callus of recent formation is not opaque to the rays, and all our skiagrams were taken at the latest within six weeks of the injury. The rays in addition to showing bullets brought out other sources of irritation—e.g., pieces of dirt and sequestra—and thus proved useful guides to a secondary operation.

The skiagrams should be taken in two different planes at right angles to each other as the body may be a mere scale or splashing of lead. This will be undiscovered in one plane and yet appear quite large in another. One English volunteer with a compound fracture of the tibia showed no bullet in Greece or on the first attempt in England, yet a large scale of lead was subsequently seen and removed. It is also important to remember that the skiagram will very likely show the bullet decidedly magnified if it is deeply situated in the tissues and some distance from the plate. This is seen in Fig. 6, where we took the bullet to be a Martini but it proved to be a small bore bullet. Since the apparent size of the bullet cannot be smaller than the real, if a bullet shows smaller than a certain calibre it is safe to say that it is not a bullet of that calibre; it is only in the opposite direction that mistakes occur. Conversely, if in any case we know what bullet has entered, its size on the skiagram will give us a rough clue to its depth. The track of the lead bullet in several skiagrams is marked by a number of small opaque points on the plate. These we do not remember to have seen previously described and think them to be small pieces of lead rubbed off the bullet in its course. There is no doubt that the belief that he has a bullet inside him even when false will worry a patient and keep him back. By taking a skiagram, having previously laid a wire on the skin to show on the plate, one can convince these sceptics that no bullet is there with immediate alleviation of symptoms.

The illustrations are given in order to show that even inexperienced hands working under considerable difficulties can get fair results rather than on account of any intrinsic merit, and also as a record of the first skiagrams taken in war time. All the original skiagrams were shown at the annual meeting of the Roentgen Society in the autumn of 1897. The reproductions in Figs. 1 to 8 are very accurate except that the bullets in Fig. 1 and Fig. 7 stand out too white and prominent. Even in the originals, however, they show with almost startling clearness and with their sharp definition of outline are much more conspicuous than any of the bones around them. The other fault is that the reproductions do not show certain details, especially the white marks in the course of the bullets and details at the line of fracture. The exposures were long as compared with our present ideas, but of course to show a bullet in bone the exposure should be longer than to show the bone alone as the bone must be penetrated by the rays. We no doubt made many mistakes of technique, at the details of which neither of us profess to be proficient. Besides those figured the most interesting cases were as follows: A wound of the shoulder in which the bullet could not be found. The skiagram showed a bullet just above the spine of the scapula near its vertebral border. This was subsequently removed. A bullet wound of the back of the thigh passing downwards. The patient had so much pain below the head of the fibula that the surgeon in charge explored the outer side of the leg here. Nothing was found and the case was brought to us. The skiagram showed a shrapnel ball in the soft parts on the outer side of the upper part of the popliteal space. This was cut down upon and found to be lying in contact with the external popliteal nerve which was pressed on but uninjured. In a case in which we had every reason to believe there was a bullet at the back of the orbit we failed altogether to see it either in a skiagram or on the screen. Many of the fractures skiagraphed showed interesting points, the main features of which have been described above.

THE SKIAGRAMS.

Fig. 1 is a skiagram of a bullet wound of the right wrist (Martini). There was a large wound situated above the base of the styloid process of the radius anteriorly. There was great swelling of the wrist and hand, especially on the radial side, and the bullet could not be certainly felt; movements at the wrist were very limited and there was no grating in the joint. The skiagram shows a fracture of the lower end of the radius with the comparatively transparent track or groove through this bone, which is widened, the bullet lying over the carpus and between the bases of the second and third metacarpals, which are uninjured. The original shows the bullet track marked by numerous white dots (? scrapings of lead). (Tube, 8 in.; exposure, 4 minutes.)

Fig. 2 shows the same hand as in Fig. 1 but taken at right angles. The skiagram shows the great thickening of the wrist and hand and that *the bullet is lying near the dorsal surface* with its distal end nearer the skin, thus keeping the direction in which it had entered the wrist. Slight flattening is seen on that side of the head of the bullet which first struck the bone. The case had been previously treated in a Greek hospital. The bullet was removed.

Fig. 3 represents a penetrating bullet wound of the hand (Martini). There were large ragged wounds of entry and exit with much damage to the soft parts. The skiagram, taken six weeks after the injury, shows oblique fractures of the second and third metacarpals. The callus scarcely shows. In the original the bullet track is plainly marked by (?) lead splashings. Taken through gauze and bandages. (Tube, 10 in.; exposure, 7 min. Case 40.)

Fig. 4 represents a penetrating bullet wound of the forearm. The bullet had passed from the outer side of the back of the forearm to the inner side of the front of the wrist. The holes of entry and exit were small. The skiagram shows the actual point of passage of the bullet between the bones with loss of substance in each filled with new bone. Oblique fractures of both bones pass upwards from here, the much more oblique one of the radius falling into a more nearly transverse one higher up the bone, thus separating a wedge-shaped piece on the ulnar side. The lower end of the ulna is slightly tilted. Very little callus. (Exposure, 6 min. Case 54.)

Fig. 5 shows a bullet wound of the forearm. The wound had been opened up by a Greek surgeon who had resected a broken piece of radius with its periosteum. The skiagram shows a gap in the radius exactly corresponding to this. The body seen among the muscles is therefore part of a bullet altered in shape. There was a hole of exit, so part of the bullet had escaped. The end of the lower fragment shows some bone thrown out by the damaged periosteum.

Fig. 6 represents a compound fracture of the humerus. The wound of entrance (small) was internal to the anterior axillary fold below the second rib. There was another wound at the back of the deltoid near its insertion and thought to be the wound of exit. The humerus was extensively comminuted in its second quarter. There was slight suppuration from the posterior wound and much callus. The humerus became enormously thickened, this thickening extending a long way down the bone. A small piece of bullet was removed from the exit wound. A body—callus or bullet—was felt in front of the fracture. The skiagram shows the bullet with flattened end on the inner side of the humerus at the upper edge of the callus. Its course from the wound of entrance can be made out in the original by lead marks. The opaque white patch behind the humerus is due to discharge from the posterior wound damaging the paper and shows the position of the sinus. The great sheath and second outline around the humerus was thought to be false and due to movement. It, however, appeared exactly the same at a second attempt and must be the callus, with which it corresponds and which was certainly remarkable in extent. The bullet was removed and proved to be a Mauser. (Case 63.)

Fig 7 represents a bullet wound of the left lung The wound of entrance was in front of the left shoulder joint The patient developed pneumonia then pleurisy with effusion The serum became offensive, a rib was resected and the empyema was drained, but by the finger no bullet could be felt The skiagram was taken nine weeks after receipt of the injury It shows a Martini bullet lying pointing downwards and inwards over the eighth rib on a level with the lower angle of the scapula and extending inwards to the tips of the transverse processes The white opacity of the bullet is exaggerated in the reproduction, but it stands out with clear definition in the original The patient recovered The bullet was not removed The body was much emaciated (Exposure, 25 minutes Case 21)

Fig 8 shows a bullet in the femur (Martini) The wound of entrance was in the back of the thigh and quickly healed The symptoms and the pain were slight The case had been treated by a Greek surgeon The bullet lies antero-posteriorly in the femur, apex forward It is at the level of the upper border of the patella and therefore much below the line of reflexion of the upper pouch The outline of the anterior surface of the femur is quite clean cut and there appears to have been no splintering here There was considerable damage to the posterior surface which was better seen in the original Looking with the screen in plane at right angles to this the bullet was seen to lie in the femur somewhat to the inner side (Exposure 35 min)

(To be continued)

"LETTER" WITHOUT "WORD" BLINDNESS.[1]

BY JAMES HINSHELWOOD, M A , M D , F F P S, GLASG ,
SURGEON TO THE GLASGOW EYE INFIRMARY DISPENSARY
PHYSICIAN TO THE WESTERN INFIRMARY, AND
ASSISTANT TO THE PROFESSOR OF CLINICAL
MEDICINE IN THE UNIVERSITY OF
GLASGOW

IN three preceding papers[2] on word blindness and its varieties certain views have been expressed which, in my opinion, afford the only reasonable explanation of all the varieties of this condition which are met with Since the last paper my attention has been drawn to a rare form where the patient is able to read *words* but not the individual letters of which the words are composed—i e , "letter" without "word" blindness Recorded cases of this variety are excessively rare and my attention was specially drawn to it by the occurrence of two cases in the *Western Infirmary* of Glasgow Since the occurrence of such cases forms powerful clinical evidence *in support* of the views maintained in the *preceding papers* I have *thought* that a critical examination of the visual phenomena manifested in this little known *variety—' letter ' without* "word" blindness—would prove an interesting appendix *to the series* of papers already published I have to thank Professor Sir William T Gairdner and Dr James Finlayson for their kind permission to quote their as yet unpublished cases and also to express *my great obligations* to their assistants, Dr James Carslaw and Dr John Love, who supplied me with every *facility for studying them* These cases were somewhat complex and the following must *not* be regarded as in any sense a complete report of them but simply as very brief *records* of the chief visual phenomena, that being the only aspect of these cases which concerns us in the present paper

CASE 1 (Abbreviated from the notes *supplied* by Dr John Love)—A young man, aged twenty four years, was admitted to Dr Finlayson s wards in the *Western Infirmary* on March 19th, 1898 About four months previously his illness had begun *somewhat suddenly* with severe headache vomiting, and feverishness with stiffness of the neck and back and *some* deafness Shortly thereafter there developed paralysis of the right arm, leg, and the *right side of the face*, with aphasia and profound apathy from which, however, he could be roused The history and *development* of the *case* suggested that it was most probably a sporadic example of cerebro spinal meningitis though rash was absent Improvement was very gradual both as regards the general state and the paralysis and aphasia, When admitted into the Western Infirmary there were still present some paresis of the right side and a trace of loss of power about the right angle of the mouth He had still aphasia which was motor or articulative in part and partly amnesic There was a gradual improvement in his speech during his residence in hospital and before dismissal he could converse with the other patients and nurses There was no word deafness, all requests being quite promptly obeyed His visual symptoms were somewhat remarkable There was no object blindness as he could indicate by pantomime the use of articles presented to him and he could recognise by sight pictures, colours, and geometrical forms When tested with words and letters it was evident that a peculiar condition was present On testing him with letters it was found that he could neither read nor write a single letter of the alphabet except "T," which he generally recognised and always named "Tom" which was his own name Nor could he point out any named letter except "T " The inability to recognise them was the same with all sizes and forms of letters both written and printed On testing him with words, however, in a large number of trials it was quite evident that he could read almost every word presented to him, even words of three or four syllables and very unfamiliar ones, while at the same time he was quite unable to name or point out a single letter of the word he had just read Such words as "stethoscope " "telescope," "electricity," "infirmary," &c , were read at once The word "*JOB*" was read at once, but when the *letters* were arranged "OBJ" and he was asked to read them he could not name a single one The contrast between the fluency with which he read the words and his inability to make anything out of the individual letters was very striking Substantives he could make out much better than verbs and could read them with the greatest fluency. Slight intentional mistakes in spelling and even reversing letters were not observed by the patient who read the words just as if no alteration had been made and did not seem conscious of anything peculiar about the word Numerals he recognised and named as far as "nine," but not beyond that, and only the Arabic numerals and not the *Roman* *There was no amusia* ; the patient could name and intone correctly the signs of the new notation but could not name them as letters of the alphabet During his residence in hospital the patient's power of reading words improved so that when he was shown to the Glasgow Medico Chirurgical Society on May 6th, 1898, he could interpret correctly any request in printing or writing and was able to read a letter written by himself He had been instructed to educate himself by learning the letters of the alphabet again This was done but only with partial success When he left the hospital about three months after admission he was able to recognise some letters but only occasionally and with many failures He could write a few letters to dictation but he made many mistakes On May 2nd he wrote the following letter which he was able to read afterwards —

> DEAR MOTHER,—Please send my clothes to-morrow and my boots as I am getting on the grounds I am keeping better hoping you are well

He addressed the letter quite correctly On attempting to write the alphabet from memory he wrote as follows — "a b, c, d e, i j h, m, n, s, u, w, v, y, z,' and the following letters being dictated he wrote as follows —

Dictated b	wrote l	Dictated c,	wrote c
j	l	,, f (failed)	
, p (failed)		, d,	wrote a
, r (failed)		,, n (failed)	

Numerous trials as to his power of writing and reading individual letters were *made but the above may be taken* as a fair sample of the measure of success attending these trials While he failed with many of the letters he wrote readily words beginning with the same letters In the above trial he failed to write "p," "r," or "n," but wrote quite readily "pot " "Robert," "nail,' and so on He left hospital at the end of May and has not been seen since the above examination was made, so *that nothing can be said* as to his further progress

As a parallel to this case I will briefly quote a case reported by Dr Byrom Bramwell,[3] selecting only those features of it which specially interest us in the present paper.

[3] Edinburgh Medical Journal, 1897, p. 241

CASE 2.—A man, aged sixty years, was suddenly seized with loss of power of the right hand and arm with aphasia on Dec. 22nd, 1886. On March 9th, 1887, he came under observation with paralysis of the right hand and arm, considerable motor aphasia but no word-deafness. There was partial right homonymous hemianopsia. "The patient," says Dr. Bramwell, "is unable to recognise a single letter of the alphabet; he can neither spontaneously name the letter when it is shown to him nor can he when the names of the different letters are repeated aloud to him indicate when the particular letter which he is asked to recognise is named. He is unable to recognise figures either spontaneously or when they are named to him. Soon after the patient first came under my observation his wife who always accompanied him when he came to see me stated that he was able to read and make out some things which interested him in the newspapers. I paid very little attention to this statement, for it is well known that aphasic patients who are utterly unable to read a single word not unfrequently occupy themselves with a book or a paper and appear to their friends to be intelligently interested. Knowing that this patient was unable to read a single letter of the alphabet I paid no attention to this statement. When, however, his wife stated on a subsequent occasion that he had when walking in the cemetery read to her the names (with which, be it observed, he had not been previously acquainted) on some of the tombstones correctly and also that he had on another occasion turned up and pointed out in a guide-book the name of a landlord about whose property they were talking my attention was aroused and I found on investigation that the patient could read many words the individual letters of which he was totally ignorant of even when they were named to him. Thus on June 1st he read correctly the words which I had written to him on a piece of paper, but he was totally ignorant of the individual letters composing the words which he was able to read and did not know them when they were named."

CASE 3.—A case of somewhat similar character to the two preceding ones but in which the letter-blindness was not so complete has been recorded by Broca. Not having been able to see the original report of this case I quote it from Brissaud's article on Aphasia.[4] "A patient may suffer from letter-blindness and not from word-blindness proper or he may be blind to words and not to letters. While this is true letter-blindness is, as a rule, accompanied by word-blindness. That letter-blindness may exist without word-blindness is illustrated by a case reported by Broca. This patient was attacked by partial letter-blindness—that is to say, he had lost the visual memories of some letters. He could read words, however, in which were letters he did not know and one could change the place of letters in a word or even suppress some without his perceiving it."

CASE 4. (Abbreviated from notes supplied by Dr. James Carslaw.)—On Jan. 18th, 1898, a young married woman, aged thirty years, had a sudden attack of right hemiplegia with aphasia. She was admitted to Professor Sir W. T. Gairdner's wards in the Western Infirmary on Feb. 1st. She was found to be seven months pregnant; she had a previous history of rheumatism and the physical signs of mitral obstruction. She had right hemiplegia, the leg, arm, and face being involved. There was complete motor aphasia which remained persistent during her whole stay in hospital, the patient only being able to say two or three words on dismissal. There was no word-deafness. There was complete word- and letter-blindness on admission, the patient being unable to recognise any word, letter, or figure, printed or written. From this word-blindness there was a gradual recovery and when tested on June 8th, a month before her dismissal, she recognised all the words submitted to her and all the letters of the alphabet and figures in any combination. From the period of her admission the power of recognising words, letters, and figures was very carefully tested from time to time. These successive examinations elicited the remarkable fact that there was not a simultaneous improvement in her power of recognising the various forms of printed and written characters but that she first acquired the power of recognising numerals, then words, and last of all the individual letters of the alphabet. This progress will be most vividly seen by briefly quoting extracts from the ward journals bearing on this point. "Feb. 1st: The patient was unable to recognise any printed or written words, letters, or figures." "Feb. 22nd: If the page of a book is read aloud to the patient she can follow with her finger and point to the last word when a stop is made. She fails, however, to detect intentional mistakes made when reading. She can pick out with her finger a word here and there. She cannot point out a single letter of the alphabet except 'a' which she generally recognises correctly. She now recognises the Arabic numerals." "March 7th: The patient can now apparently understand printed matter though some words seem to puzzle her. She can follow with her finger as the page is read and detect intentional mistakes fairly well. She can now pick out a few letters of the alphabet but with very variable accuracy. Arabic numerals are recognised at once both individually and in combinations up to 100, but beyond this she has difficulty." The patient was now dismissed owing to her approaching confinement and was readmitted in May. The next examination was made therefore after an interval of about two months. "May 16th: The patient recognises words correctly and easily. She often indicates the recognition of the word by pointing to the corresponding object. She can with greater accuracy than before correct mistakes intentionally made in reading. She does not, however, readily detect slight mistakes in spelling—e.g., 'chiar' for chair—though she at once points to the object indicated. The individual letters composing the words are not, however, easily recognised; and when asked to point out individual letters of the alphabet she makes very many mistakes. She makes fewer mistakes with the small letters than with the capitals. She recognises Arabic numerals correctly and quickly, and to higher figures than formerly, but not Roman figures." "June 8th: The patient now recognises printed and written words rapidly and correctly. She quickly indicates with her finger any intentional mistakes made in reading aloud to her. She at once points to any word named. She can now pick out all the individual letters of the alphabet both small and capital. She recognises Arabic numerals in any combination and now also recognises Roman figures. In short she has now regained the power of recognition of all the printed and written characters with which she was previously familiar." The patient was dismissed on July 9th.

CASE 5.—As a parallel to this case where the patient, completely word- and letter-blind, recovered the power of reading words before letters I can quote briefly a case reported by Dr. MacVicar at a meeting of the Forfarshire Medical Association on Feb. 4th, 1898.[5] The patient was a young man, a painter by trade, who had received a fair education. His head was struck forcibly against the edge of a dresser on Dec. 27th, 1897, the injury being over the right parietal eminence. He suffered from symptoms of concussion and after recovery from this was unable to read. He gradually improved and was able to read aloud and wrote to dictation short words before he could recognise letters. He understood "written speech" subsequently to being able to read aloud. He could read simple sentences in fourteen days and numerals in nineteen days after the injury. The lesion was supposed to be of the nature of a hæmorrhage due to *contre-coup* over the left angular gyrus and possibly affecting the supra-marginal and posterior part of the third temporo-sphenoidal convolutions.

These five cases make it quite clear that there is a distinct variety of "letter-blindness" where the individual though able to read words cannot read the individual letters of which the words are composed. Recorded cases of this kind are rare and Dr. Bramwell in narrating his case remarks that he is not aware that such a condition has been previously described. The rarity of such cases, however, is, I think, chiefly owing to the circumstance that when they do occur they are not recognised. The fact of there being two in the Western Infirmary at the same time forms a strong presumption that such cases are by no means so rare as is commonly supposed. Such cases escape observation because the patients are not accurately tested as to their power of reading not only words but also individual letters. If the patient can read words the examiner may not know the necessity of also testing his power of reading letters and, conversely, if he finds the patient unable to read letters he will probably take it for granted that he is also unable to read words. If all patients were carefully tested as a matter of routine both with words and individual letters the number of recorded cases belonging to this category would be rapidly increased.

How are we to explain the at first sight startling fact that these patients whilst able to interpret words could no longer interpret the individual letters of which the words were composed? In my last paper[6] I discussed at length a class of cases exactly the converse of those at present under consideration—viz, cases in which the patients could read the individual letters but could not recognise by sight the words composed of aggregations of these letters Both classes of cases are explained in precisely the same way The fact of the existence of these two definite classes of cases, the one being the complement of the other, is the strongest possible proof of the correctness of the views set forth in detail in the last paper, where it was maintained that clinical evidence demonstrated the complete independence of the visual memories of letters and of words and that this complete functional independence could only be reasonably explained on the assumption that these distinct groups of visual memories are stored and preserved in different but probably contiguous areas of the cerebral cortex

---

[4] Traité de Médecine, Paris, 1894, tome vi., p. 241.

[5] THE LANCET, Feb. 19th, 1898.

The ability to recognise by sight the individual letters of the alphabet is acquired by the individual in a comparatively short space of time, there being only 26 letters in our alphabet, or double that number taking small letters and capitals At first we read words by spelling them out letter by letter and by thus analysing the word into its constituents of letters and syllables Individuals who have not progressed beyond this stage—i e, who read all words by analysing them into their individual letters—would necessarily become blind to words if they became blind to letters But by years of persistent labour and practice we gradually acquire and store up the visual memories of words When this stage has been reached the individual reads not by analysing each word into its individual letters but by recognising each word as a separate picture The words cease to be for such an individual simply a congeries of letters, each word is regarded rather as an ideogram, picture, or symbol which suggests a particular idea That this is the true explanation is confirmed by the facts observed in three of the preceding cases

In Cases 1, 3, and 4 slight mistakes in spelling changing the place of some of the letters and even suppressing a letter, were not noticed by the patient In Case 1 even when one or two letters in a word were reversed—such as "LOVE instead of LOVE—the patient did not seem to notice anything amiss but read the word correctly without making any remark From these observations it is clear that these patients recognised the words by their general form alone A slight alteration in one or two letters was therefore not observable so long as the general form and appearance of the word were preserved In fact these individuals recognised a word just as they recognised a landscape or a familiar face, by their general outline and form, without resolving them into their constituent details It is therefore easily conceivable how such individuals who have thus acquired by long and constant education the power of reading words by sight not phonetically but ideographically can lose the visual memory of the individual letters and yet retain the visual memory of words or, to put it briefly, such individuals may be "letter blind" without being "word blind"

In my previous papers[7] it was pointed out that in the visual memory centres the visual images or memories are arranged in definite groups having a certain *independence* of each other The visual memories of objects of places, of forms, and of colours are deposited in different brain areas from the visual memories of words letters, and figures Hence we have word and letter blindness occurring without the loss of these other forms of visual memory Further, it was argued from the clinical evidence that the visual word centre (generally regarded as occupying the left angular and supra marginal gyri) is itself complex and that *within* it are stored different groups of visual symbols—numbers words, and letters—in quite distinct but probably adjacent cerebral areas In my first paper[8] the complete independence of the visual memory of numbers from that of words and letters was proved from the clinical evidence and the conclusion was drawn that these must be deposited in separate cerebral areas Bastian,[9] in his recent admirable work on aphasia has evidently adopted this view which was argued in detail in my first paper He adds an important piece of confirmatory evidence "Destruction of the visual word-centre," he says, "is the common cause of word blindness If there should be a separate seat for the registration of numerals it is suggested that its escape from damage would account in all probability for the preservation of the ability to read and the ability to write numerals That this is the true explanation seems all the more probable because on rare occasions it has been found that loss of ability to read and comprehend numerals exists in the absence of word blindness One such case has been recorded by Trousseau and another by de Capdeville in which there was a transitory defect of this kind Now precisely the same clinical evidence can be brought forward to show the complete independence of the visual memories of words and letters In the last paper[10] four cases of great purity were quoted and discussed in which the patients *could read fluently* individual letters but not words In the present paper 5 cases are adduced in which the patients could read words but not letters The clinical evidence therefore clearly indicates the complete independence of these two groups of visual memories and hence justifies the inference that these are deposited in distinct areas of the cerebral cortex This is precisely the chain of reasoning which led to the inference that the *numerals* were stored in a separate cerebral area, and if the reasoning is sound in the case of the numerals it is equally valid in the case of the words and letters Since the visual memories of letters and words are usually lost together it is highly probable that the areas in which they are stored are contiguous When there is only partial destruction of the centre and that part of the centre in which are stored the visual memories of letters remains intact then the patient can read individual letters but not words, on the other hand, when the letter area is destroyed and the part in which are deposited the word memories is still functionally active then the patient though he cannot recognise an individual letter can recognise words just as in the cases under consideration in the present paper When the destruction of the centre is partial and irregular, part of each area being destroyed, then the patient will be able to read some words and some letters, the extent of the ability to read being dependent upon the extent of cerebral cortex within the centre which is still functionally active The cerebral area destroyed may be very irregular and hence arise those very peculiar cases of which several examples are quoted in my last paper. In fact the varieties are endless but the view here expounded is the only one which renders all these varieties intelligible

Case 4 affords a very striking confirmation of this view that the visual memories of numerals, of letters, and of words are stored in perfectly distinct though adjacent cerebral areas. The lesion in this case was almost certainly an embolism, blocking up the left middle cerebral artery, cutting off the blood supply to the left motor area, to Broca's convolution, to the visual word centre in the left angular gyrus and hence the symptoms right hemiplegia, aphasia and word blindness At the outset this patient had lost the visual memories of all the symbols printed and written—numerals, words, and letters—with which she was previously familiar That this is the condition most commonly met with is easily understood when we consider that all these visual memories are deposited in areas which though distinct are certainly close together and probably contiguous It is only when a part of the area escapes that these cases are met with where the patient retains some special group of visual memories The vascular supply of the central cortex is liable to considerable variation As a rule the visual word centre is supplied by a branch of the middle cerebral artery and here evidently this branch supplied the centre in its whole extent Hence the complete blotting out of the visual memories of numbers words, and letters In a case previously reported by me[11] the patient lost only the word memories and retained those of figures and letters Here part of the word centre was probably supplied by a branch of the posterior cerebral and hence escaped destruction This variation of vascular supply no doubt explains many of the clinical varieties of this defect which are met with In the case under consideration the visual word centre gradually recovered its functional activity, probably by a gradual restoration of the blood supply through anastomosing channels In the gradual restoration to functional activity of the centre the outstanding feature is that the patient first gained the power of recognising Arabic numerals, then words, and, last of all, individual letters. I do not know of any more convincing proof which could be brought forward to demonstrate that these different groups of visual memories are deposited in distinct cerebral areas. If the centre was simply the general repository of these visual memories without any definite grouping or arrangement of them then there would have been a gradual simultaneous recovery of numbers, words, and letters, which was not the case. On the other hand, if these three distinct groups of visual memories are deposited in definite and distinct areas within this centre, then as the blood-supply is gradually restored, enabling the successive areas to resume their functional activity, it is to be expected that the patient would regain the different groups of visual memories in successive order, as actually took place in the case under consideration. It is to be observed that the order of recovery is not from the simple to the complex but that the power of recognising words was recovered before the power of recognising letters. This order of recovery was also observed in Case 5 already briefly quoted.

[9] Aphasia and other Speech Defects p 283 London 1898

The order of events cannot therefore be explained simply by a gradually increasing functional activity of the centre as a whole, nor do I see any other way in which the phenomena observed can be intelligibly explained than on the ground of distinct areas within the centre being occupied with these different groups of visual memories—numbers, words, and letters.

In this series of four papers an attempt has been made to give some reasonable explanation of the phenomena observed in the various forms of "mind-," "word-," and "letter-blindness." The views set forth therein have been arrived at by a minute analysis of cases observed and by a critical study of the clinical observations of others. They have the merit of simplicity and of rendering more intelligible the varied and manifold phenomena met with in these conditions.

Glasgow.

A CASE OF TUMOUR OF THE UTERUS COMPLICATED BY TWIN PREGNANCY; CÆSAREAN SECTION; RECOVERY.

BY E. R. C. EARLE, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.,
GOVERNMENT MEDICAL OFFICER, LUCEA, JAMAICA.

ON August 20th, 1898, I was called to attend a black woman who had been in labour since the evening of the 18th. The labour pains were strong and frequent, but the labour had not progressed and she was in great pain. After examining the patient I ordered her to be removed at once to the Lucea Hospital with a view to the performance of Cæsarean section. The following is a short account of the case compiled from the notes taken on the hospital case sheet. I may add that I was ably assisted in this operation by Dr. C. M. Phillips and Mr. J. J. Rogers, the Government Medical Officer at Green Island.

The patient was a black woman, about thirty years of age, and was admitted into the hospital at 9 A.M. on August 20th, 1898. She had been in labour since the evening of the 18th. The abdomen was very much distended and the labour pains were frequent and strong. On vaginal examination a large, firm, elastic tumour was *found* occupying the pelvic brim and projecting into the upper part of the pelvic cavity. There was a space of about an inch between the anterior surface of the tumour and the symphysis pubis and a similar space on each side between the tumour and the pelvic brim. The tumour was fixed and could not be moved. The os uteri could not be felt at first, but on curving the index finger behind the symphysis and pushing it up as far as possible the os was felt above the pubes slightly to the left of the middle line. The os was partially dilated and flattened antero-posteriorly, simulating a slit-like opening, and was on a level with the upper border of the symphysis. When the patient assumed the upright position the distension of the abdomen was most noticeable and on examination per vaginam in this position the os could not be felt with the finger. Dr. Phillips and Mr. Rogers having examined the patient in consultation with me it was decided to perform Cæsarean section without delay. A vaginal douche was administered and the rectum was emptied by an enema. The urine was drawn off by a catheter and the abdominal surface was thoroughly cleansed and asepticised. Chloroform was administered at 11.15 A.M. and the operation commenced at 11.30 A.M. A vertical incision was made in the middle line 6 in. in length, from 1 in. below the umbilicus to about 2½ in. above the symphysis, and was continued through the abdominal wall, only two small arteries requiring torsion. The peritoneum was exposed and divided on a director the whole length of the wound. There was no bleeding from the abdominal wound after the two small arteries had been twisted. The uterus was brought forward into the abdominal wound and fixed there by Dr. Phillips. A vertical incision was made in the anterior wall of the uterus commencing near the fundus and extending downwards for about 4½ in.; the hæmorrhage was rather free. The membranes were ruptured and a male child was extracted by the feet, the head being delivered last. It was then found that there was another child in the womb situated behind the first, with the head at the fundus and the breech at the lower segment of the womb. This was quickly extracted, the head coming first and the legs last. There were two distinct placentæ which required a considerable amount of manipulation to extract. The hæmorrhage ceased after the placentæ were removed. It was then seen that there was a large solid fibroid tumour of the body of the uterus involving the whole of the posterior surface and right side from the fundus to the cervix and extending down behind the cervix into the pelvis. The incision happened to be made along the anterior border of the tumour, so that the left lip of the wound in the uterine wall was through normal uterine tissue and the right lip was along the edge of the tumour. There was also a smaller fibroid tumour on the left side of the uterus, of about the size of a small apple. The uterine appendages on either side appeared to be normal. The uterine tumour was 9 in. in length, 7 in. from side to side, and about 5½ in. antero-posteriorly. It was pear-shaped, being broader at the fundus and narrower at the pelvic brim. The uterine wound was closed by 5 large, deep, silk sutures passed through the uterine wall and 10 small sutures of fine silk through the peritoneum. There was no oozing through the wound after the application of the sutures. Sponges on holders were passed down into Douglas's pouch and on each side but they returned unsoiled showing that there had been no escape of blood into the

The white marks on each side of the abdominal wound are due to reflected light and not to any *discolouration* of the skin. The groove is the result of the strapping; it has now gone and the surface of the wound is level with the abdominal wall.

peritoneal cavity. The parietal peritoneum was then brought together by a continuous fine silk suture and the abdominal wound was closed by 6 large deep sutures, passed through the whole thickness of the abdominal wall, about ¾ in. apart, and about 1 in. from the edges of the wound. 10 small superficial stitches were passed through the skin alone and the wound was completely closed. There was no oozing from the wound after it was closed. No drainage tube was passed into the abdominal cavity. The wound was sprinkled with a mixture of boric acid powder and iodoform and covered with a layer of oiled silk. Over this was placed iodoform gauze, sal alembroth gauze, and lint soaked in carbolic acid lotion, and over all a layer of wood-wool dressing, the whole being kept in position by an abdominal bandage. An injection of strychnia ($\frac{1}{30}$ gr.) was given hypodermically and a morphia suppository (¼ gr.) was placed in the rectum. The operation was over at 12.30 P.M. and the woman was replaced in the bed at 1 P.M. The children were both males—one weighed 5 lb. and the other 4½ lb. They were puny, weak, and thin. When removed from the womb the first one did not breathe and the second gave only one or two gasps, but they were both thoroughly revived in ten minutes. The urine was drawn off at 5 P.M. At 4 P.M. the temperature of the patient was 100° F. and at 8 P.M. it was 101° when there was no pain, but there was a bloody discharge from the vagina. At 11 P.M. the temperature was 101° and the pulse was 114. The next day (August 21st) at 6 A.M. the temperature had declined to 99° and there was neither hæmorrhage in the vagina nor pain in the abdomen. At 10 A.M. the temperature was 100° and the pulse was 96. The vagina was douched with carbolic lotion (1 in 80). The vaginal discharge was normal and without odour. The temperature from 2 P.M. to 2 A.M. on the 22nd remained at 101° and the pulse was 108. The patient slept well on the night of the 21st. She had no hæmorrhage or pain, the lochia were normal, and she took nourishment well. At 6 A.M. the temperature was 99·4° and the pulse was 108. At 2 P.M. the temperature had risen to 101·6° and the patient complained of griping pains in the abdomen, her temperature at 6 P.M. being 102·2° and her pulse 126. The bloody discharge from the vagina was now more copious than before. A douche of carbolic lotion (1 in 80) was administered. At 10 P.M. the temperature had declined to 101°. On the 23rd the temperature at 6 A.M. was 99·4° and the patient was doing well. She had slept well at night. Her pulse was 106. The temperature at 2 P.M. was 101·4°. At 5 P.M. another douche was administered. At 10 P.M. her temperature was 101·4°. On the 24th the temperature at 6 A.M. was 100·4°. The patient had slept fairly well and had had no pain or hæmorrhage. She was, in fact, very comfortable. At 2 P.M. the temperature was 102·6°. The discharge from the vagina was copious and in large clots, but the odour was normal. The vagina was douched again. The patient complained of pain in the breasts. At 6 P.M. the temperature was 104·4° and the pulse was 122. The odour of the discharge was normal. The left breast was rather full and the tongue was slightly furred, the temperature at 9 P.M. being 102°. On the 25th the temperature at 3 A.M. had declined to 99·8° and at 7 A.M. to 99·4°. The patient had slept well, but had pain in the back. At 9.30 A.M. the wound was dressed for the first time, when there was no soiling of the dressings and the wound had partially united by first intention. The discharge from the vagina was free and normal and the pulse was good. The temperature at 4 P.M. was 103·2° and the pulse was 106. At midnight the temperature was 103°. On the 26th at 6 A.M. a soap-and-water enema was administered. The lochia were greenish in colour but normal and there was no pain in the breasts. The temperature was 102° and the pulse was 106. At 5 P.M. the temperature was 103·4° and at 11 P.M. it was 101°. On the 27th at 6 A.M. one large and four small stitches were removed. A slight amount of thin purulent fluid exuded from one of the large stitches. The temperature was 102° and the pulse was 114. At 1.30 P.M. the temperature was 103·2° and at 9 P.M. it was 101·6°. On the 28th at 7 P.M. an enema was given and the bowels were freely opened. The temperature was 101·2° and at 1.10 P.M. it was 102·6°. On the 29th I found that she had passed a restless night and this morning she lost the power of motion on the left side and her speech was indistinct. There was pain in the right side of the chest and the back. The wound was dressed and

The patient rapidly recovered the power of motion and of speech. The lochia were less but were normal. Both lungs were found to be much congested at the bases at the back. The temperature at 7 A.M. was 101° and at 4 P.M. 102·4°. On August 30th the patient's condition was better. Her speech was clear, the abdominal wound was healing, and the vaginal discharge was normal. The temperature at 9 A.M. was 101·4° and at 10 P.M. it was 102·6°. The pulse at 9 A.M. was 98. On the 31st the temperature kept at 101° during the day, and on Sept. 1st, at 9 A.M., it was 99·6° with a pulse of 92. At 5 P.M. the temperature became normal and remained so on the 2nd with a pulse of 86. On the 3rd it was 99·4° all the day and the patient was much improved and stronger. The improvement continuing, on the 4th four stitches were removed. The wound was healing. From this day until the 10th the temperature did not rise above 99·4°. On that day at 6 P.M. it was 101·4° and at 10 P.M. it was 102°, with a pulse of 120. On the 11th the temperature became normal and the pulse was normal also. The abdominal wound was now quite healed and the uterine tumour was much smaller. On the 15th the patient began to walk about the ward and on the 20th she was discharged.

This case of Cæsarean section is interesting in many ways. It shows in a remarkable manner the fact that the presence of a large fibroid tumour of the body of the womb of the dimensions above mentioned did not interfere with the progress of a twin pregnancy to the full term, nor did it prevent the normal uterine tissue from contracting and retracting firmly after the removal of its contents as shown by the normal amount of lochia passed during the puerperium. The only abnormal symptom which occurred was the continued high temperature which was undoubtedly due to the severe congestion of the lungs which lasted for some days. A dose of sulphate of quinine (30 gr.) was given daily during the pyrexia and hot linseed meal poultices were applied to the back and front of the chest and after the pulmonary congestion had subsided the chest was wrapped in cotton wool. During the fever the lochia remained perfectly normal and she never had any symptoms to be referred to the womb itself. The abdominal wound healed without any trouble with the exception that a slight amount of pus collected in two of the larger stitches which was caused by tension. After the tension was relieved by strapping the wound healed readily. The bowels were opened on August 26th by a soap-and-water enema and on Sept. 1st they acted normally. The urine was drawn off by a catheter every five hours until Sept 2nd when she first passed it of her own accord and continued to do so afterwards. Another interesting feature in this case was the remarkable and rapid diminution in size of the fibroid tumour after the operation. A month after the operation it was only about one-third of its original size. This was probably due to the gradual decrease in the blood-supply. The twins were thin, ill-nourished, and weak. I am inclined to think that this was caused by the tumour which used up for its own support a considerable portion of the blood-supply which would otherwise have been devoted to the nourishment of the placentæ. After the pregnancy had ceased and the blood-supply of the uterus had decreased the tumour also rapidly became smaller. The twins are alive at the time of writing (seven weeks after the operation). One of them is strong and healthy but the other is weak and thin and is evidently very delicate. The mother is quite well and strong and the fibroid tumour is causing her no inconvenience.

Lucea, Jamaica

A CASE OF OPERATION FOR EXTREME MYOPIA.

BY ROBERT BRUDENELL CARTER, F.R.C.S. ENG.,
CONSULTING OPHTHALMIC SURGEON TO ST. GEORGE'S HOSPITAL.

THE possibility of curing a high degree of myopia by the removal of the transparent crystalline lens has of course been present to the minds of ophthalmic surgeons from the time when the refraction of the eye first received careful consideration, but until recently the risks of the operation were rightly held to outweigh the prospects of benefit from on as primary affection. He thought that it might occur secondarily to hypertrophy of the ventricle in men who were accustomed to great muscular exertion.—Mr. PAGE said that he had formerly seen much of the work of the late Dr. H. G. Sutton and he recalled that he insisted on the fact that aneurysm did not cause hypertrophy of the ventricle.—Dr. ROLLESTON thought that aortic aneurysm was nearly always due to atheroma, and not to increased strain as by high arterial tension, &c. He did not think that simple hypertrophy would give rise to aneurysm, as suggested by Dr. Taylor, unless there was pre-existing disease of the coats.—Dr. H. A. CALEY asked as to the frequency of syphilis among the patients. Was syphilis more common among the younger patients and arterio-sclerosis among the older ones?—Dr. NORMAN MOORE entirely agreed with Dr. Calvert. He insisted that the methods of examination should be exact. The presence or absence of hypertrophy could only be satisfactorily settled by weighing the heart, and arterio-sclerosis could not be excluded unless the kidneys had been microscopically examined.—Dr. CAUTLEY said that the weight of the patient should also be recorded to compare with the weight of the heart in order to form an accurate measure of the hypertrophy. He thought that atheroma was the effect rather than the cause of increased tension. A little outward displacement of the apex beat did not necessarily indicate hypertrophy, as it might be due to mechanical displacement of the heart by the aneurysm.—Dr. CALVERT, in reply, said that he looked on atheroma as an indication of high tension and that the latter gave rise to hypertrophy. If the atheroma gave rise to definite roughening of the coats there might be some obstruction to the flow of blood.

Dr. H. G. TURNEY and Mr. C. A. BALLANCE related a case of Aortic Aneurysm in which there was involvement of spinal sensory nerve roots, and sudden paraplegia for which laminectomy was performed. The patient was a man, aged thirty-five years, who was admitted to St. Thomas's Hospital on Sept. 14th, 1897. He had had a hard chancre seventeen years before admission. Two years before he began to suffer from pain in the middle of the back of an aching character, not constant at first but becoming so later. It soon extended round his body at the same level. For the last four months the pain had been continuous and severe; movement had no effect upon it. Morphia had been necessary to relieve it, and he had lost 2 st. in weight during the four months before his admission. On admission he was seen to be a powerfully-built man, but he was thin, and he had a well-marked expression of pain on his face. He complained in a wailing voice of intense pain in the upper abdomen and back. There was no loss of power or affection of sensation in the extremities. All the reflexes were normal. His mental condition was clear. He referred his pain to a triangular area situated between the fifth rib and the ensiform cartilage on the right side in front. The skin in this area was intensely hyperæsthetic with well-defined borders; a similar condition had been present in the corresponding triangle on the left side, but this part was normal at the date of admission. The rigidity of the back at once attracted attention; it was more marked in the upper half of the spine. There was also a distinct deformity; the site of maximal projection was occupied by the seventh and eighth dorsal spines. The tenth spine was extremely tender. There was no sign of visceral disease in either chest or abdomen. Antispecific treatment was adopted, but without change in the patient's condition. On Oct. 11th the hyperæsthesia was transferred to the left side and there was some difficulty in swallowing solid food. On Oct. 23rd, while the patient was being washed in bed, he called out with intense pain and instantaneously lost power and feeling in his legs. The paraplegia remaining unaltered on the following morning laminectomy was performed. The body of the seventh dorsal vertebra was found to have completely disappeared, its place being occupied by recent clot. The finger was passed into the clot and no hæmorrhage occurred. Death took place ten hours after the operation. At the necropsy a large aneurysm was found arising from the descending aorta on its posterior aspect, situated exactly in the middle line and causing destruction of both vertebræ and intervertebral discs from the sixth to the ninth dorsal. The diagnosis was believed to rest mainly between aneurysm, caries, and new growth, but no final conclusion seemed to be possible even at the operation. The remarkable features of the case were: (1) the insuperable difficulties in the way of a correct diagnosis; (2) the passage of the finger into an aortic aneurysm without hæmorrhage; (3) the localisation of certain sensory areas; and (4) the unusual destruction of the intervertebral discs equally with the vertebral bodies from pressure.—The PRESIDENT asked for the exact reasons for operating, as the diagnosis before the operation seemed to be that there was a growth? He said that he had no faith in the hot sponge as a test of caries.—Mr. PAGE thought that the clinical history seemed to suggest that rupture of the aneurysm might have been the cause of the sudden paraplegia. He agreed with the President as to the worthlessness of the hot sponge test.—Dr. TURNEY, in reply, said that at the time of the operation the diagnosis was not clear and laminectomy was performed to relieve pressure on the cord. This was so far successful that the lower intercostal muscles which had been paralysed before the operation resumed their function.

MEDICAL SOCIETY OF LONDON.

The Conduct of the Heart in the Face of Difficulties.

A MEETING of this society was held on Jan. 9th, the President, Mr. EDMUND OWEN, being in the chair.

The PRESIDENT proposed that a letter of condolence should be sent to the relatives of the late Dr. Hare, who had been a Fellow of the society since 1850, Lettsomian Lecturer in 1861, and President in 1866.

Sir WILLIAM BROADBENT read a paper on the Conduct of the Heart in the Face of Difficulties. He said that he had taken this subject at the request of the President who had asked him to deal with the behaviour of the heart itself as well as its management by the physician. Sir William Broadbent said that many of the difficulties of the heart were not of its own making but were imposed on it from outside, as by pressure of a dilated stomach, of a pleural effusion, or of an aneurysm. In other cases the difficulty was due to peripheral resistance, as in cases of high arterial tension. If pressure were gradual the heart suffered little embarrassment, beating, for example, with fair force when so much displaced by a left pleural effusion that the apex beat was felt under the right nipple. But a sudden displacement by the occurrence of pneumothorax or rapid dilatation of the stomach was attended by great embarrassment and dyspnœa. Probably flatulent distension of the stomach caused in the mass more suffering than actual heart disease. The heart had special relations with both the cerebro-spinal and sympathetic systems and in some individuals owing to undue nervous excitability mental or emotional excitement or even indigestion gave rise to disproportionate reflex effect on the heart. When there was pain it was often difficult to diagnose whether it was due to external causes or not. The absence of physical signs would help, but even where there was some valvular lesion flatulent distension might be responsible for the pain. Even angina might be simulated, but that at first came on with exertion, while the spurious form came on during repose. A weak heart might even be brought to a standstill. In women angina pectoris was almost always spurious. If any symptom could be "walked off" it might be put down as functional, as might be an intermittence of the pulse of which the patient was conscious. Patients with functional derangements of the heart often to their own hurt made them an excuse for avoiding exercise and for taking stimulants. One of the most common difficulties was due to high arterial tension. This was apt to give rise not only to salutary hypertrophy but to increase of fibrous tissue which afterwards might degenerate, the valves in some cases suffering before the heart muscle. It should be remembered that digitalis, by constricting the arterioles, raised the tension and might increase the strain. With regard to the difficulties in the case of valvular disease the first thing was to ascertain the amount of mitral regurgitation or of aortic constriction. If there was no accentuation of the pulmonary second sound there was no need to interfere with the patient's mode of life. If there were no dyspnœa but there was good compensation nothing need be done, but the patient must be warned that any sudden or excessive exertion might cause a break-down. But in cases where there was mitral regurgitation with enlargement of the liver and anasarca and scanty and albuminous urine, the first thing was to relieve the right side of the heart. There was nothing which relieved the heart so marvellously as venesection, but in these degenerate days it was difficult to employ it. As an alternative six or eight leeches might be applied over the enlarged liver. Either should be followed by a smart purge. When the right side had been relieved digitalis might be given with excellent effect. The anasarca might be relieved by Southey's tubes and the pleura should be aspirated early. The principle of treatment was to get rid of the difficulties rather than to urge the heart on to more violent efforts to overcome them.

The PRESIDENT asked whether when Sir William Broadbent spoke of these degenerate days he referred to patients or to practitioners.

Dr. A. E. SANSOM said that he was entirely in agreement with Sir William Broadbent's contentions. He remarked on the extreme tolerance of the heart muscle. A case had even been recorded in which it was alleged that a wound of the right ventricle had been successfully sutured and another in which a bullet was found embedded in the heart muscle of a man aged seventy years where it had lain for a long time without causing inconvenience. He thought that perhaps too much importance was attached to the muscle itself. The most extreme fatty degeneration was seen in cases of anæmia and yet if the anæmia in those cases had been relieved no doubt the fatty degeneration would have passed off. The nervous relations were of even greater importance than the condition of the muscle. He protested against the routine administration of digitalis in heart disease and suggested that the abuse of cardiac tonics was sometimes responsible for sudden death in patients suffering from valvular heart disease.

Dr. THEODORE WILLIAMS mentioned a case in which from distension of the stomach the patient became actually livid and apparently in great danger. The relief of the flatulence led to almost complete disappearance of the symptoms. The neuroses of the heart were very difficult to treat. He mentioned a case which he believed to have been one of spurious angina in which the attacks alternated with attacks of asthma. The patient ultimately died suddenly. As to the tolerance of the heart muscle he related the case of a child who ran a needle into the chest through the intercostal space, apparently wounding the heart. It was removed by Sir John Erichsen and there were no symptoms. In another case of which he knew a man was wounded by an assegai in the heart and did not get surgical attention for half an hour, but he made a perfect recovery.

Dr. ALEXANDER MORISON asked whether Sir W. Broadbent still held to his belief in the occurrence of non-synchronous action of the ventricles. He quoted a case showing the rapid therapeutic effect of strophanthus and nux vomica in a case of ascites and anasarca complicated with albuminuria and diabetes. He remarked that the three factors of the functional activity of the heart—nerves, muscle, and blood—must not be dissociated. He agreed about venesection and said that the smallest quantity which should be taken away should be 4 oz.—a "heartful of blood."

Dr. SYMES THOMPSON said that in functional disorders there was a great tendency for the patient to exaggerate his troubles and possibly for the medical man to under-estimate the amount of distress. He quite agreed that in cases of heart embarrassment the important thing was to diminish its labour. The late Sir George Johnson taught that in cases of acute kidney trouble it was wrong to stimulate the kidney, but it should be relieved of some of its work, and the same was true of the heart. Venesection or a mercurial dose followed by a saline purge should precede the employment of cardiac tonics.

Dr. R. MAGUIRE thought that one of the causes of difficulty was variation in the negative intrathoracic tension. In emphysema the amount of dyspnœa was often out of proportion to the extent of lung disabled and might be due to lessened excursion of the chest wall and less suction action. He thought that the pulsus paradoxus could be ascribed to increase of this negative pressure. In most people it could be produced by throwing the shoulders back and taking a gasping inspiration. Probably many intermittent pulses where one beat was missed in five were really instances of pulsus paradoxus produced in this manner.

Dr. CALVERT said that senega was often employed in mixtures as a "stimulant expectorant." It was, however, a cardiac depressant and if as much of the active principle as would be taken by a man in the day were injected into a cat it would die at once from cardiac failure. It had the further disadvantage that it was a decided irritant to the stomach.

Dr. ROBERT JONES asked whether toxins formed in the body could have any direct effect on the heart. He mentioned a case in which there was great rise of pulse-rate during the status epilepticus, and subsequently acute fatty degeneration of the heart muscle was found.

Dr. H. A. CALEY asked whether the heart failure in cases of high arterial tension and dilatation of the stomach might not be due to a toxæmic condition and as to whether interference with the coronary circulation leading to disturbance of the nutrition of the heart wall might not be one of the important factors.

Sir WILLIAM BROADBENT, in reply, said that in the case of dilated stomach the mechanical nature of the interference with the heart's action was proved by the immediate relief which followed eructation. He thought that there was nothing to compare with venesection in severe cases, and would take not 4 but 12, 16, or even 20 oz. and sometimes would repeat it. As illustrating the tolerance of the heart muscle he mentioned a case in which a needle, probably introduced in early childhood, was found transfixing the septum ventriculorum. He did not think that the fatty degeneration found in cases of anæmia was of the same nature as that found when there was blocking of the coronary arteries. In the latter the muscle was much more soft and friable. He mentioned a case in which a man consulted him suffering from cardiac embarrassment associated with dilatation of the stomach. Instead of going to bed he took a journey, ate a heavy dinner, and died almost immediately after. He still thought that in cases in which all the heart beats did not reach the wrist there was non-synchronous action of the ventricles. When there was a systolic murmur present it was only audible with the beat which reached the wrist. In one case where a thrombus was subsequently found in one of the ventricles only one beat in five reached the wrist. He attributed the cessation of the pulse when a gasping inspiration was taken, as mentioned by Dr. Maguire, to suction on the left auricle preventing the ventricle from filling.

OBSTETRICAL SOCIETY OF LONDON.

Ectopic Gestation.—Vulvar Discharges in Children.—Exhibition of Specimens.

A MEETING of this society was held on Jan. 4th, Dr. C. J. CULLINGWORTH, President, being in the chair.

Dr. ARCHIBALD DONALD read a paper on a case of Ectopic Gestation at the Seventh Month in which the Fœtus was Extracted by Vaginal Incision. The patient, aged thirty-three years, was admitted to St. Mary's Hospital, Manchester, on July 20th, 1898. She had been married about a year and had been regular till Jan. 20th. In February she had a slight discharge which in March existed continuously for three weeks. On admission the abdomen was uniformly enlarged by a tumour which reached about four inches above the umbilicus. A loud souffle was distinctly heard. The cervix was close to the pubes and the uterus could be mapped out bimanually in front and to the left and seemed of about the size of a two months pregnant uterus. The posterior vaginal fornix was bulged by a hard mass which almost filled the brim; this mass was the fœtal head in which the sutures could be felt. On August 18th, 1898, abdominal section was performed and the placenta was exposed. The wound was therefore temporarily covered and the child was delivered through a posterior vaginal incision by cranioclasm and the sac packed from the vagina with iodoform gauze. Alarming hæmorrhage occurred when the gauze was removed on the fourth day. The separation of the placenta occupied some weeks, but the patient made a good recovery and was discharged strong and well on Nov. 12th. The author described the position of the fœtus in the broad ligament and discussed the advantages of the vaginal route.—Dr. GALABIN said that in intra-ligamentous pregnancy the vaginal methods of operating when practicable secured several advantages obviating the necessity of stitching the sac to the abdominal wall, and any temporary sinus caused little inconvenience. In several cases of extra-uterine gestation of shorter duration than seven months he had adopted the plan followed by Dr. Donald of making an exploratory abdominal section and, if the case proved to be one of intra-ligamentous pregnancy unruptured or if the pelvis was completely shut off by adhesions, opening the sac per vaginam. The advantage of abdominal exploration was shown in one case where the sac had been ruptured and a large quantity of blood was effused into the peritoneal cavity. He had removed the placenta in one case through the vaginal incision three days after the operation and the patient rapidly convalesced.—The PRESIDENT said that Dr. Donald could already lay claim to be considered as a pioneer in the treatment of early ectopic gestation by operation through the vagina and he had now brought before the society a case of advanced ectopic gestation treated by the same method. Dr. Herman had collected several instances in which in the years gone by an extra-uterine fœtus had been extracted through an opening in the vaginal roof, but Dr. Donald by opening the abdomen had completed and made certain the diagnosis and had thus made himself master of the situation. He (the President) asked if any opinion had been formed as to the source of the hæmorrhage?—Dr. DONALD, in reply, said that Dr. Walls who was responsible for the after-treatment of the case believed that the hæmorrhage came from a placental vessel. Though he had not discussed in his paper early tubal pregnancy he (Dr. Donald) expressed the opinion that the vaginal incision was safer than the abdominal in early cases—i.e., up to the third month.

Dr. DRUMMOND ROBINSON gave the results of his investigation of 50 cases of so-called Vulvitis in Children. The condition was found to be most common in children under five years of age, common between the ages of five and ten years, and uncommon in children who were over ten years of age. In 41 of the cases (76 per cent.) the pus cells of the discharges contained cocci which presented characters which, as far as is known, are peculiar to the gonococcus of Neisser. The contagious character of the discharge was illustrated by several cases. The chief symptoms were painful micturition and pruritus vulvæ; occasional complications were ophthalmia, peritonitis, and arthritis. In most cases the inflammation appeared to be superficial to the hymen. Dr. Robinson expressed the opinion that the majority of cases of vulvitis in children were probably gonorrhœal in origin.—Dr. BOXALL said that it seemed to him remarkable, if the whole of the 41 cases were to be regarded as gonorrhœal, that only 1 showed evidence of conjunctivitis.—Dr. SNELL said that he had seen several cases of vulvitis in children occurring in families where in all probability gonorrhœal infection was impossible. The subjects were usually weakly but the complaint was easily and quickly cured.—Dr. A. ROUTH thought that though at present these diplococci were indistinguishable from gonococci it would be found that they were not really identical. He thought that vaginitis might be caused by infection from the vulva during incautious examinations.—The PRESIDENT said that Dr. Robinson's paper was important from the scientific and from the practical medico-legal aspects. He asked whether by culture experiments Dr. Robinson had confirmed the diagnosis? He called attention to a paper published in 1859 by the late Sir W. Wilde on some medico-legal aspects of purulent discharge in children. In Dr. Robinson's cases pain on micturition was recorded as a common symptom; might not this be due to the inflamed state of the vulva and not to urethritis which was not an essential feature in acute gonorrhœa in the female? Vaginitis was comparatively rare in the gonorrhœa of the adult.—Dr. HANDFIELD-JONES found it difficult to believe that over 70 per cent. of all vulvar discharges in children depended on gonorrhœal infection. The following points seemed to him to render the gonorrhœal theory doubtful: (1) the disease had not spread to neighbouring tissues; (2) it was readily cured; (3) the inguinal glands were rarely enlarged; (4) the disease was common in delicate children and rare in the robust; and (5) in undoubted infection by rape the disease was much more severe than in ordinary cases of vulvitis.—Dr. ROBINSON, in reply, stated that he did not think that the absence of vaginitis in these cases was an argument against their gonorrhœal nature as vaginitis was rare in gonorrhœa in the adult. He did not agree with Dr. Handfield-Jones that most of these children were sickly; on the contrary, they were generally in excellent health. Absence of enlargement of the inguinal glands and the ease with which the disease was cured showed that the disease differed from that in adults. His views were based not on the clinical aspects of the cases but upon bacteriological investigation.

The following specimens were shown:—

Dr. LEA: A Uterine Tumour expelled during delivery.

Dr. ADDINSELL: Microscopical Sections of an Ovary and Tube removed for the relief of intermenstrual pain.

Dr. AMAND ROUTH: Early Pregnancy in the Uterus of a bitch.

Dr. BOXALL: Dermoid Tumours of both Ovaries.

HARVEIAN SOCIETY OF LONDON.

Formation of Adhesions in the Joints, the Peritoneal Cavity, and Elsewhere.

A MEETING of this society was held on Jan. 5th, Dr. ROBERT BOXALL being in the chair.

Mr. HOWARD MARSH read a paper, entitled, "On the Subsequent History of Cases in which Adhesions have formed in the Joints, the Peritoneal Cavity, and elsewhere." He remarked that adhesions were identical with the new connective tissue formed to repair wounds and were apt to result under various circumstances when the tissues were maintained in a condition of irritation. Their extent and firmness depended on the activity and duration of the inflammatory process in which the parts concerned were involved. One of the chief laws regulating the production of new tissue in the healing of wounds was that of conformity to type. In other words, new material served the purpose of, as far as possible, restoring structures to their typical or original state. To this end in an aseptic wound only just so much as was required was produced. But when the tissues were maintained in a condition of inflammation new material was organised in superfluous amount and in such parts as the joints and the peritoneum accumulated in the form of adhesions. Such adhesions, however, played no part in the restoration of the structures to their typical condition. On the contrary, they were abnormal and while they remained true or complete repair—that is, restitution to type—could not take place. Before repair could be perfect they must be got rid of, just as the superfluous callus (termed temporary) formed in the repair of a fracture was removed. Now this result was provided for. Undoubtedly adhesions if not too extensive and firm tended to be absorbed. This result, though often met with in the joints, was most obvious in the peritoneum. Many cases had been met with in which after pelvic cellulitis or tuberculous peritonitis extensive adhesions completely disappeared. A typical case was related. A middle-aged woman, after peri-uterine inflammation, suffered so much pain and flatulent distension, accompanied by attacks of constipation and vomiting, that an exploratory laparotomy was performed, when it was found that the intestinal coils were so extensively and firmly matted together that nothing could be done. The patient, however, gradually improved. Two years later laparotomy was undertaken for the removal of an ovarian cyst. It was then observed that almost every trace of adhesions had disappeared. Now the existence of this strong natural tendency to the absorption of adhesions—like the absorption of temporary callus—was a very important fact in respect both to prognosis and the management of clinical cases. It was, indeed, the key to the treatment of many joints whose movements were restricted by adhesions, either in their interior or in the surrounding parts. In this connexion cases must be systematically divided into three groups in the order of their severity. In the first group, where adhesions were the result of inflammation neither severe nor prolonged, such adhesions as were developed soon spontaneously disappeared and the joint regained its free range of movement. In the second, in which inflammation had been more active and prolonged, the adhesions were so extensive and firm that unless surgical interference was adopted they remained and rendered the joint permanently stiff. Here it was necessary to manipulate the joint under an anæsthetic so that the adhesions were ruptured; and to follow this proceeding up by the use of passive movements and massage. Under this method of treatment absorption would occur. The third group included cases in which as the result of acute inflammation extending over some weeks the structures of the joint had been destroyed and replaced by very extensive and firm adhesions so that the joint was virtually converted into a scar. In such cases manipulation could do no good. The scar might of course be torn through but the only result would be that as soon as the scar re-formed the loss of movement would be more complete than ever. In practice, before treatment could be determined upon, it was obviously necessary to ascertain to which group the particular case in hand belonged. This could generally be done by taking into account the cause of the inflammation in which the joint had been involved, the degree and duration of the inflammatory process, and the present symptoms. In cases of traumatic inflammation not severe and not of long duration and now unattended with heat and pain movement would probably be restored as soon as the joint was gently exercised. In the second group the same favourable result would follow manipulation massage, hot douching, &c. It was this group in which formerly so many oversights had occurred in surgical practice and so many cases had been put right by the rough and ready wrenchings of the bone setter. Nor were such oversights even yet entirely ancient history. In the third group, typical of which were joints which had been involved in septic inflammation following parturition and some of the forms of gonorrhœal arthritis, the joint was a mere scar and manipulation was perfectly useless and not a little dangerous. In the great majority of tuberculous cases at whatever stage manipulation was not advisable or even safe. In conclusion, Mr Marsh gave a warning as to massage. In every case in which this method was ordered the surgeon should give precise directions and closely supervise the manner in which they were carried out. He had met with not a few instances in which cases handed over for massage had either, as a mere matter of commerce or ignorantly, although quite conscientiously, been greatly over treated and some severely injured. In the keen competition of the present day not only had massage been sometimes carried too far and even degraded to vile purposes, but it and other methods, good in themselves when duly supervised, had been exploited on a commercial basis and worked by limited liability companies. Doubtless the public had a full right to please themselves. It was, however, necessary under the circumstances that surgeons should study cases under their care as fully as possible and critically discriminate between various groups, and that they should take care into whose hands, whether for massage or any other form of treatment, they, so far as they were responsible, allowed their cases to pass. Many a wolf with a sheep's skin on its back was the embodiment, in the credulous eyes of the public, of an angel of light.

Mr ALBAN DORAN observed that they did not know how far the endothelium in serous and synovial membranes was destroyed by inflammation nor how far it was capable of repair. Destruction of the endothelium greatly facilitated the formation of firm adhesions. Delbet had shown in the thirty-fifth volume of the *Annales de Gynécologie* that rough handling and antiseptic solutions damaged or destroyed the endothelium of the peritoneum. In septic inflammation of a serous membrane the tissues which renovated the endothelium were probably destroyed. On the other hand, long standing tuberculous peritonitis seemed far less destructive, as Mr Marsh had noted in tuberculous disease of joints. Mr Doran had operated frequently for tuberculous peritonitis, one patient died a few years later from phthisis and the small intestines which had been matted together at the operation were found almost free after death except in the pelvis.

Mr HORACE MANDERS remarked that it was evident that the first stages of inflammation were frequently induced by traumatic disturbance without any influence from microbes, perhaps they were not all in accord as to the precise meaning of the term "inflammation." He thought that Mr Marsh had pointed out, with great clearness as regards treatment, that in cases of simple plastic inflammation with excess of callus the surgeon could dominate the injury by manipulation or operation, keeping out microbic invasions by aseptic precautions, but in cases of adhesive inflammation of joints due to microbic infection a different condition obtained and any attempt at manipulation always failed. This Mr Manders believed to be due to the fact that the tissues, especially the endothelium were dissolved by the toxins secreted by these microbes whether tubercle bacilli, streptococci, or gonococci, and that until a means could be found of neutralising these toxins the microbes which had taken the initiative remained masters of the situation.

Dr BOXALL remarked that the effusion of thick plastic lymph into the peritoneum like the provisional callus around a bone was a wise provision of nature which often served to shut off the general peritoneal cavity and protect it from injury. Having served its purposes, this effusion in the majority of cases became subsequently almost completely absorbed. The reason why in some cases but not in others the process of repair seemed to run riot so that one or more firm bands of adhesion were left was by no means clear.

LIVERPOOL MEDICAL INSTITUTION.

Perforating Ulcer of the Stomach.—Myxœdema treated with Colloid.—Exhibition of Cases and Specimens.—The Vaccination Act of 1898.

A MEETING of this society was held on Jan. 5th, the President, Dr MACFIE CAMPBELL, being in the chair.

Mr. ROBERT JONES related the histories of two cases operated upon for Perforating Gastric Ulcer, one of which recovered and the other died fourteen days after operation. In the first case a woman, aged nineteen years, the perforation had existed for three hours and was situated on the posterior aspect near the pylorus. Some partially digested milk had exuded. There was no peritonitis. The ulcer was inverted and stitched and the wound closed without drainage. She made an uninterrupted recovery. From the appearance of the ulcer, absence of anæmia, and previous history of tubercle, Mr. Jones suggested the possibility of the tuberculous nature of the ulcer. The second case, a woman, aged twenty one years, was operated upon fourteen hours after perforation; she was very collapsed and a large indurated perforation was found near the cardiac end of the lesser curvature on the anterior aspect. There was exudation of partially digested food. Adhesions had formed to the liver and abdominal parietes. There was considerable exudation of lymph which had to be forcibly scraped. The ulcer was obliterated by a purse string suture, fortified by Lembert stitches and completed by stitching omentum over the area. She progressed fairly well for fourteen days when she vomited pus. An incision was made and a perisplenic abscess containing foul pus was found. She was very collapsed and died twelve hours later. A post mortem examination showed the perforation to have quite healed. There was no communication between the wound area and the perisplenic and sub-diaphragmatic abscess cavities. The diaphragm was burrowed through and the lung opened into. There was no ulcer on the posterior aspect of the stomach. Mr. Jones agreed with the recent suggestion of Mr F. Furner that the lesser sac of peritoneum should be irrigated and the posterior aspect of the stomach inspected in nearly all cases.—Mr. FRANK T. PAUL, while fully agreeing with Mr Jones as to the value of early operation, thought it was sometimes possible to attain success after a longer delay than twenty-four hours. Stomach fluids in the peritoneal cavity were much less virulent than intestinal matter, the general depression was much less and the inflammatory changes were more plastic. He advised more pains to be spent in drying out the peritoneal cavity than in flushing it, a complete and thorough flushing was impossible. When the soiling was general a drainage tube should be put in Douglas's pouch through a separate opening. In Mr Jones's second case, a difficult and severe one, he thought it had been dealt with most ingeniously and it was only through an accident that its ultimate success was marred.

Dr BUCHANAN related a case of Myxœdema in a man, aged fifty four years treated with "colloid" matter according to Dr R. Hutchinson's formula. The disappearance of symptoms was shown to be remarkable, and after four months' treatment the restoration to health was complete. The case was illustrated by a series of lantern slides demonstrating in a marked degree the condition of the patient before and while undergoing treatment.

Dr ALEXANDER showed a Calvarium from a man aged twenty four years, who was brought to the parish infirmary by the police from an hotel in the city. He had been found lying on a bed semi conscious and bleeding slightly from one nostril. A revolver was found on the floor with one chamber empty; there was no mark of any injury on his face or any discolouration from powder. He remained in a semi conscious condition and died the day after admission. Post mortem there was found a scarred fracture of the external table of the frontal bone around which the periosteum was raised. On opening the skull a fracture of the cribriform plate of the ethmoid was found and a bullet was discovered in the brain substance above, it had impinged on the internal table making only a small indentation. The frontal lobes were much damaged.

Dr BRIGGS showed a specimen of a Uterine Fibroid weighing 13½ lb removed from a single woman aged thirty-three years. The operation was performed on Nov

1898, through an abdominal incision by hysterectomy, of which enucleation was the first step.

Dr. N. E. Roberts read a paper on the Vaccination Act, 1898, and the Local Government Board Order of Oct. 18th. He deplored the attitude of hostility which large sections of the community had assumed towards vaccination. There could be no doubt that these good people had given them a fall and repudiated them and their work in the matter of vaccination. Not until some great calamity occurred would this insane agitation be stifled; meanwhile they were drifting into a position of great danger. He particularly deplored the fact that large numbers of objectors were animated by a high enthusiasm, regarding their action as a kind of holy war, in a neighbouring town thousands crowding for exemption certificates singing "Christians Awake" and other appropriate hymns. He explained the provisions of the Act and Order and appealed for cordial relations between the public vaccinators and the private vaccinators under the somewhat trying circumstances of the public officer having to visit the homes.—The President in opening the debate said that probably no more retrograde step had ever been taken by Parliament—a step by which the majority had been handed over bound hand and foot to a fanatical minority. Calf lymph, be thought, was responsible for a certain amount of insufficient vaccination. He had used calf lymph exclusively during the last fifteen years and required to operate a second time in about 15 per cent.; this gave rise to dissatisfaction among the friends. What, again, was to be done with cases in which only one or two marks took? He generally recommended revaccination in four or five years. The importance of cleanliness in skin and instruments was now well understood and everything should be done to remove prejudice against the operation.—Mr. Rushton Parker said that in England the public seemed determined to take the risk of small-pox for some of their children. Whether the Government were wise or not in adopting the recent Vaccination Act it was evident that they were, as individuals, staunch adherents of vaccination and only adopted this Act as being in their expectation more likely in the long run to maintain the practice of vaccination than the order for its compulsion upon a democratic community who largely refused to be coerced in this matter.—Dr. Hugh R. Jones called attention to two statements in the report of the Royal Commission—that vaccination was protective against small-pox and that vaccination could not be replaced at present efficiently by other preventive measures. There was, however, another side; isolation, notification and disinfection, as subsidiary measures, ought to receive their full credit and the hope of the future for the extinction of infectious diseases depended chiefly upon efficient sanitary measures.—Dr. Hope considered that the present grave condition in respect to vaccination was contributed to by the very long period, extending over many years, which the Royal Commission took before publishing their conclusions. During these years the opponents of vaccination were extremely active and unfortunately very successful. He pointed out that the Bill introduced by Mr. Chaplin differed very widely from the Act as passed—an Act which was in absolute and direct antagonism to the carefully considered recommendations of the Royal Commission whose exact words were: "We are of opinion that the State ought to promote the vaccination of the people"; and again, "We can see nothing to warrant the conclusion that in this country vaccination might safely be abandoned and replaced by a system of isolation."—Dr. Smart, Dr. Archer, Dr. Permewan, Dr. Hill, and Dr. Grünbaum spoke.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Acute Infective Inflammation in Bone.—Exhibition of Cases.

A meeting of this society was held on Dec. 21st, 1898, Mr. Pryce, President, being in the chair.

Mr. Morley Willis read a paper on Acute Infective Inflammation in Bone. The difficulty attending the early diagnosis of this condition was remarked upon and stress was laid upon tenderness of the bone in the neighbourhood of an epiphysis, taken in conjunction with the other signs of acute disease, as being an important aid in forming an opinion. The pathology, it was stated, was usually an acute infective osteomyelitis developing near the epiphyseal line where pathological changes are prone to occur. Acting on this idea of the origin of the disease the treatment should consist of not merely incising the periosteum, but trephining the shaft of the bone near the epiphyseal line, enlarging the opening if necessary, and removing all the acutely inflamed medulla, irrigating with some efficient antiseptic, and lightly packing with gauze. A case was related which showed the futility of the treatment which stopped short when the periosteum had been incised; the disease spread to the knee-joint and the leg had to be subsequently amputated. This it was believed might have been averted had the bone been trephined in the first place.—Mr. Chicken did not share the views expressed by Mr. Willis as to the pathology of the disease.—Mr. Mackie related a case in which suppurative pericarditis followed the necrosis of a long bone; the pericardium was opened and drained and the patient made a complete recovery.—Mr. A. R. Anderson and the President also discussed the paper.—Mr. Willis replied.

Dr. W. B. Ransom showed:—1. A patient (and read notes of the case) who had been affected with Paralysis of the whole of the Left Side, including the Face, together with the Right Leg. His symptoms pointed, it was thought, to a thrombosis of the basilar artery, but he had completely recovered under treatment, only a very slight weakness of the left hand remaining and that was diminishing. 2. A Brain showing Sarcoma of the Cortex. The patient had improved for a time under iodide of potassium but then became worse. Operation was undertaken but removal of the whole growth was impossible. 3. The Brain of a patient who had suffered from Aphasia which was discovered to have been due to thrombosis of the central branches of the Sylvian artery.

Mr. A. R. Anderson showed:—1. A patient after Pylorectomy. The duration of the symptoms had been only three months according to the patient's statement. They had consisted of vomiting and pain. No blood had been vomited. There was great dilatation of the stomach at the time of operation. Previously to operation the stomach was washed out. The growth was excised and union between the stomach and the duodenum was effected by sutures only. The operation lasted 1 hour and 5 minutes. Food was given by the mouth on the third day after operation. The patient left the hospital perfectly well in every respect and had remained so up to the present time. A section of the growth showed it to be a spheroidal cell carcinoma undergoing colloid change. 2. Osteo-sarcoma of the Fibula removed by operation. 3. Notes of a case of Transperitoneal Uretero-lithotomy. This case was one in which the symptoms simulated closely those of appendicitis of which there had been apparently several attacks. An operation for appendicitis was undertaken in a quiescent interval; the appendix was found to be quite healthy and normal but on feeling about a stone was discovered in the right ureter at the brim of the pelvis. The original wound was closed and allowed to heal and when this had occurred another operation was undertaken for the removal of the stone in the ureter. An incision was made in the right linea semilunaris and the bowels being kept out of the way with sponges the ureter was incised and three small stones were removed which formed a chain. The lowest one was of uric acid and the other two were of phosphatic nature, soft and crumbling. The ureter was then closed by a continuous suture and a flap of peritoneum was brought over the wound and sutured in that position. The abdominal wound was then closed. Recovery was uneventful and complete and the patient remains perfectly well.

Mr. Chicken showed:—1. The patient and photograph of a case of Congenital Obstruction of the Ethmoidal Infundibula. An incision down the centre of the bridge of the nose was made and the nasal bones were separated. A communication was then established between the middle meatus of the nose and the ethmoidal cells by drilling. The nasal bones were brought back into place and the wound was stitched. Only a faint scar remains and the result has been good, but one side shows some signs of a tendency for the passage to close. 2. Some Abnormal Semilunar Cartilages. These had been removed from the knees of different patients and were undergoing absorption. In some cases they had been nearly loose and Mr. Chicken thought it probable that this was one source of loose bodies in the knee-joint. 3. Skiagrams of Three Ununited Fractures Produced by Direct Violence. They had all been wired with a successful result in each case. 4 *Two specimens of Necrosed Bone* One a minute sequestrum, was found in the centre of the shaft of a tibia in a small abscess cavity containing at the time of operation only a little caseous material The other consisted of the entire circumference and a considerable length of the shaft and had been removed by operation, having been divided into two pieces to facilitate removal

BRADFORD MEDICO CHIRURGICAL SOCIETY.

Ovarian Tumours —Operative Treatment of Cancer of the Breast —Hæmatoporphyrin in the Urine

A MEETING of this society was held at the Royal Infirmary, Bradford, on Dec 20th, 1898, the President, Dr BERRY, being in the chair.

Dr EURICH gave a demonstration of microscopic sections from a series of Ovarian Tumours He mentioned that the malignant or non malignant character of a tumour could not be determined until an operation had been performed, also that in the same tumour there could be demonstrated a change from an innocent to a malignant type, and further that in the ovary itself, although it might not apparently be involved in the tumour, yet malignant disease might be demonstrated microscopically —Mr J B HALL remarked that a tumour might exist for years without showing symptoms of malignancy and he advocated early removal of all tumours as soon as they were diagnosed

Mr J B HALL read a paper on the Operative Treatment of Cancer of the Breast He expressed the opinion that there was a brighter future for the surgical treatment of cancer of the breast than for that of any other form of malignant disease, provided only that the disease was recognised early and that a thoroughly radical operation was performed Mr Hall contended that the bad results of operations in the past had arisen from imperfect removal and he pointed out how greatly the percentages of cures had increased since the introduction of the more extensive methods of operation The aseptic treatment of wounds rendered it now possible to perform these operations without grave risk to life He then gave a summary of the results of operations performed by various surgeons from 1870 to 1898 and contrasted the ratio of cures (5 per cent) which were obtained by Billroth with that (from 50 to 60 per cent) which had been obtained by Halsted, Watson Cheyne and others in the last few years Billroth's cases published in 1878 showed an immediate mortality of 24 per cent., while Halsted's series of 133 cases which had occurred between 1889 and 1898 recovered without any death arising from the operation and in 1897 Bennett May recorded 68 cases without a single fatal result Allusion was made to the researches of Heidenhain, Stiles, and others on the course of the lymphatics of the breast, and the conclusion arrived at was that no operation could be deemed satisfactory unless not only the breast and axillary glands were removed but also the lymphatic channels which run in the pectoral fascia Halsted's operation was selected as fulfilling these requirements, and a description of this operation was given and diagrams were shown to illustrate the steps in the procedure Mr Hall stated that very little loss of function followed the operation and that it was generally possible owing to the large mass of tissue removed to cover in the wound without undue tension on the skin. He said that in the older method of operating the pectoral muscle after being stripped of its fascia became much infiltrated with fibrous tissue and consequently it suffered considerable loss of function The idea that the operation would be accompanied by an increased immediate mortality was negatived by the experience of operators who had used it Mr. Hall contended that in consequence of the contents of the axilla being fully exposed to view, and considering also the possibility of employing the scalpel and the forceps instead of the finger, by no other method could they be so easily and safely removed He then discussed the question of operating in cases which were too far advanced to hope for a cure and advocated operation as a palliative measure in all cases where there was a reasonable prospect of removing the whole growth and in which operative interference would not be exceedingly dangerous to life or leave a hopeless functional lesion —Mr HORROCKS remarked that he thought that in most cases the operation was unnecessarily severe and that the pectoral fascia could be removed without removing the whole muscle. He said that the results of operation in cases of atrophic scirrhus should not be grouped with the results observed in rapidly growing cases as the prognosis was so much more favourable He thought that statistics of mixed cases were consequently unreliable — Mr AITHORP said that the more favourable results obtained in later years as compared with the operations in earlier cases were partly due to improvement in operative technique whereby the immediate mortality of the operations was much reduced —The PRESIDENT asked if it was a fact that cases in which suppuration occurred were more likely to be followed by a cure than those in which primary healing followed —Dr HIME, Dr WOOD Dr BELL, and Dr. ARNOLD EVANS also took part in the discussion —In reply Mr HALL expressed the opinion that it was not possible to remove the pectoral fascia completely while leaving the muscle behind He said that possibly the apparently better result in cases which suppurated was due to the circumstance that the suppuration might possibly be produced by a very extensive handling and bruising of the tissues consequent on an extensive operation

Dr J H BELL read notes of a case in which Hæmatoporphyrin had appeared in the Urine The case was one of nervous affection accompanied by insomnia and sulphonal (in 10 gr doses) had been given to induce sleep, but the patient had continued the administration when no longer under medical supervision

---

THE ODONTOLOGICAL SOCIETY OF GREAT BRITAIN —An ordinary meeting of this society was held on Jan 9th at 40 Leicester square —The Treasurer presented the balance sheet for the year ending Oct 31st, 1898 which showed the finances of the society to be in a satisfactory condition —Mr Badcock brought forward a case in which the right maxillary third molar communicated with the antrum The patient in question complained of slight pain in the region of the right molars and an examination of the teeth showed the existence of a cavity on the mesial side of the third molar the pulp cavity being in a septic condition The tooth was extracted with but little difficulty and on the patient rinsing his mouth the water was found to pass through his nose A lotion of boracic acid was prescribed and no subsequent trouble occurred Mr Badcock stated that he had been unable to find any similar case recorded —In connexion with this communication Mr Redman exhibited a dried specimen in which the roots of the third molar opened into the antrum —Mr Baldwin exhibited several instruments of his own designing which he had found useful in practice —Mr H. Lloyd Williams exhibited a small modification of Hammond's splint which he had used for some years for fractures of the mandible, far back, where only one tooth, usually the third molar, remained in the smaller fragment —Mr J H Mummery read a paper on the Teeth of Echeneis (sucking fish) He stated that the lower jaw in occlusion projects far beyond the upper so that the anterior upper row of teeth shut almost entirely behind the whole of the teeth on the dentary bone in the lower jaw This upper row of teeth occupied the anterior border of the intermaxillary bones, projecting almost horizontally forwards The teeth were much longer than elsewhere in the mouth and of a very different shape They are flattened antero posteriorly, slightly expanded at the base narrowing upwards and expanding again into a curious spatula or hoe shaped crown strongly recurved and prolonged on the mesial side into a point. Behind the angle of the mouth there is a broken line of seven or eight teeth prolonged to the extremity of the inter maxillary bone These scattered teeth are of a quite distinct shape from those above described and resemble those in all other parts of the mouth—their shape is conical and they are very sharply recurved with sharp-pointed enamel tips Behind the spatula shaped teeth there is an imperfect scattered row of conical incurved teeth on the intermaxillary bones The vomer is thickly beset with teeth of the same description The teeth of the lower jaw occupy the dentary bone and the lingual bone, teeth being also present upon the inferior pharyngeal bones, the bronchial arches and the superior pharyngeals The lower teeth are arranged in four or five more or less distinct rows, the larger teeth occupying the front row and the smaller the inner row. The whole series of lower teeth is interrupted at the symphysis by an edentulous space about the width of two of the larger teeth. The lingual bone is covered with minute teeth arranged in lines radiating from behind forwards; these teeth are uniform in size and on microscopical examination are seen to have the same shape as the other teeth of the lower jaw. The inferior pharyngeal bones are crowded with minute teeth of the same shape and structure. On the concave surfaces of the bronchial arches looking towards the gullet are three or four rows of bony processes or tubercles arranged at regular intervals and covered with similar minute conical teeth. The armature of the mouth is completed by similar minute recurved teeth covering the superior pharyngeal bones. The mode of attachment is quite distinct from that described in any other fish of the family Scomberidæ. Each tooth—and the description applies to all the teeth in the mouth, including those upon the tongue and branchial arches—is attached to the summit of a special bone of attachment but is not anchylosed to it; it slides freely upon the bone and exhibits a modified form of hinge. The summit of this process of bone is in the form of a convex ring slightly raised on one side, resembling the ball of a ball-and-socket joint with the centre cut out leaving an elevated ring of bone. The base of the tooth is accurately adapted to this surface and slides easily upon it. A capsular ligament surrounds the whole. It will be seen that this arrangement would allow of a sliding movement of the tooth on the bone of attachment in every direction, but the ring of bone being slightly more elevated on the anterior aspect the motion is limited in this direction more than in the opposite, and the tooth can be bent over much more in the direction of its point than in any other direction; the strong ligamentous band being stretched no doubt serving to draw the tooth into position again.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—An ordinary meeting of this society was held in the Society's rooms at the West London Hospital on Jan. 6th, Dr. S. D. Clippingdale, President, being in the chair.—Mr. R. Lake read a paper on the Treatment of Laryngeal Phthisis based on a series of 160 cases. He did not enter into any discussion of methods of treatment which he had not tested. Clinically the cases could be resolved into groups each of which derived benefit from slight modifications of treatment. He particularly dwelt upon the advantages of intra-tracheal injections in cases of superficial ulceration and slight swelling, but admitted its uselessness alone in cases of greater severity. —The paper was discussed by the President, Mr. McAdam Eccles, Mr. B. James, and Dr. T. R. Atkinson.—Mr. J. R. Lunn read a paper on Two Cases of Double Optic Neuritis associated with Mastoid Disease. The first case was that of a boy, aged eleven years. The patient complained of giddiness and severe pain in the right ear from which there was a little offensive discharge and he appeared to be quite deaf. Behind the right ear was a fluctuating swelling. In two days the boy became delirious and then maniacal and the swelling behind the ear became larger. Under an anæsthetic a perforation of the membrana tympani was discovered through which a drop of pus oozed. The mastoid cells were trephined and were full of offensive, cheesy matter. The operation was necessarily extensive and, at the end of the excavation the pulsating lateral sinus could be seen. The patient made a good recovery and the optic neuritis quickly cleared up. The second case was that of a girl, aged fourteen years, who had suffered from ear trouble since an attack of measles and scarlet fever when seven years old. Behind the right ear was a fluctuating swelling and from the meatus flowed an offensive discharge. Deafness was marked. The right membrana tympani was perforated. Both optic discs showed signs of optic neuritis. The right mastoid process was trephined and much sclerosed bone had to be removed before the offensive caseous matter could be reached. This patient also made a good recovery and the optic neuritis soon disappeared.—The paper was discussed by the President, Mr. R. Lake, and Dr. R. D. Batten.—Dr. James Allan showed a specimen of Hypertrophied Prepuce.—Dr. Allan also read a paper on Twelve Cases of Tracheotomy for Laryngeal Diphtheria in Young Children with Nine Recoveries. The details of the operation were discussed and stress was laid on those points which he considered important. It was shown by reference to a case that tracheotomy sometimes gave the most brilliant results in apparently hopeless cases. The indications for the operation were discussed and the dictum "When in doubt operate at once" was quoted with approval.—The paper was discussed by the President, Dr. C. Gibbs, Mr. Lunn, Mr. R. Lloyd, Dr. T. R. Atkinson, and Mr. McAdam Eccles.

Reviews and Notices of Books.

A Manual of the Practice of Medicine. By FREDERICK TAYLOR, M.D., F.R.C.P. Lond. Fifth edition. London: J. & A. Churchill. 1898. Pp. 1002. Price 16*s.*

THE ever-widening area of medical science imposes no small task upon authors of text-books, especially when these works have gained the favour of the student world, for such popularity means the frequent production of a new edition and each such edition implies revision and the exercise of much judgment in curtailment here or expansion there, according to the direction in which medicine is growing. Dr. Taylor's manual is one which has deservedly obtained much favour, so that the appearance of a fifth edition within a comparatively short time is not surprising. We are glad, also, to observe that advantage has been taken of this to publish the book in a form more worthy of its character. The pages have been increased in size as well as the type. The author, too, has subjected the work to very thorough revision, rendering it most compendious and accurate and fully abreast of modern knowledge. Thus several additions have been made to the sections dealing with infectious diseases—e.g., in malarial fevers, dysentery, diphtheria, and cholera. The sections upon Diseases of the Nervous System are especially noteworthy for the systematic and exhaustive manner in which these affections are described and analysed. The diseases of the blood and of the ductless glands have given occasion for the introduction of much new matter and the account of diseases of the urinary organs is preceded by a useful account of the urine and of the characteristics of Bright's disease. It is enough to say that the book is one which thoroughly meets the needs of the student who will find it a reliable and useful guide to the medicine of to-day.

Ovariotomy and Abdominal Surgery. By HARRISON CRIPPS, F.R.C.S. Eng., Operator for Abdominal Sections to the Ward for Diseases of Women in St. Bartholomew's Hospital, &c. London: J. & A. Churchill. 1898. Pp. 624. 8vo. Price 25*s.*

FOR many years a great controversy has raged as to whether gynæcological operations should be performed by the gynæcologist or should be handed over to the general surgeon. Into the consideration of the respective merits of the rival claimants we do not now intend to enter; but as the large majority of the treatises dealing with ovariotomy and kindred operations have been written by gynæcologists it is of great interest to see these subjects treated by a general surgeon.

Mr. Harrison Cripps commences with a useful account of the anatomy of the abdomen and pelvis, and 12 excellent plates (for the most part coloured) of the structures described add materially to the value of this chapter. The author next proceeds to describe the preparations necessary for an abdominal section, and appropriately he gives an account of the arrangements in the operating theatre attached to the gynæcological ward at St. Bartholomew's Hospital. He considers that a skylight is essential, but it should not be made to open, for draughts and dust are necessary consequences and if hermetically closed the ropes and pulleys are also avoided. Even for opening side windows the author prefers a rod working in a brass attachment on the window frame, as likely to be less septic. The walls of the theatre are of alabaster and the corners are all rounded. The ceiling is of Parian cement painted with three coats of white paint and the floor is of marble mosaic and is made to slope to one corner where is a small trapped pipe. The top of the operating table consists of a shallow copper tray three inches deep covered with an inch-thick plate-glass slab. The tray is filled with water at 130° F., and the temperature falls but little even during a prolonged operation. The water tray will not permit the inclination of the table for the Trendelenburg position, and when this is desired an adjustable top is employed. Mr. Cripps has designed a semi-circular glass-topped table to carry the instruments; it fits round the operator as he stands on the right side of the patient and in addition to holding the instruments within easy reach "it has the advantage of being a polite method of preventing spectators from crowding over the operator's shoulder." Mr. Cripps has been so frequently asked during the last few years by old pupils as to the best methods of fitting up an operating theatre in accordance with modern views that the description of the theatre given in this volume is more detailed than it would otherwise have been. For all abdominal operations the author greatly prefers chloroform to ether, as he considers that the latter does not give such thorough relaxation of the muscles, and is liable to cause venous congestion, and especially because ether sometimes produces a severe and persistent bronchitis.

The chapter on the Diagnosis of Ovarian Tumours is decidedly good and should prove of value to those who have not had much experience. Often the diagnosis of an ovarian cyst is as simple as it can possibly be, but occasionally the tumour may defy all the diacritical acumen of the most experienced gynæcologist. In the operation of ovariotomy Mr. Cripps prefers an incision not exactly in the middle line, but a little to one side or the other of the tendinous raphe. By the bye, why does Mr. Cripps always write "tendonous"? He does not consider that a long incision is any more liable to lead to a ventral hernia than is a short incision and he therefore advises that it should be freely lengthened if necessary. After the removal of a cyst from between the layers of the broad ligament it is often recommended that the edges of the open capsule should be fixed to the borders of the wound. With this advice Mr. Cripps says that he cannot agree, as a cavity is thereby left which otherwise would not exist, and with this opinion we are inclined to concur. A difficulty is often experienced in inserting a Keith's drainage-tube into the deepest part of Douglas's pouch on account of the intestine occupying this cavity. Mr. Cripps gives a useful practical suggestion which we do not remember to have seen before. He advises that the tube should be passed down while the water used for flushing is still in the pelvis.

Silkworm gut sutures are in the author's opinion the best and they should be of the stoutness of salmon gut; they should be passed through the whole thickness of the abdominal wound and care should be taken that the sutures pierce the peritoneum not farther than one-sixth of an inch from the edge, for if a broad piece of the serous membrane be included it gets drawn up between the muscular surfaces and Mr. Cripps believes this to be often a cause of a local scar and a hernial protrusion. When a Keith's drainage-tube has been employed it is frequently a difficult matter to decide when to remove it. Intestinal obstruction may result from pressure of the tube and two cases of this are quoted; on the other hand the drain may be removed too early and that is especially likely to occur in cases in which any suppuration has been present.

Of the many complications which may supervene after an ovariotomy or other abdominal section vomiting is perhaps the most troublesome, and if it does not yield to treatment in two or three days the life of the patient is in imminent danger. The abdominal distension in itself is increasing the exhaustion and the chance of benefit from an exploratory laparotomy is indeed remote. Under these circumstances Mr. Cripps advises enterotomy performed through a small incision over the right iliac fossa. A fresh incision is preferable to reopening the original wound as septic infection of the peritoneum is less likely and it is more easy to reach a portion of the small intestine near the ileo-cæcal valve.

A good account is given of Cæsarean Section and the author expresses himself strongly in favour of applying two rows of sutures, one deep and the other superficial, through the uterine wall. Champneys's method of preventing a future pregnancy is recommended; it consists in ligaturing a loop of the Fallopian tube and cutting off the knuckle on the distal side of the ligature.

It is a necessary consequence of the conditions under which this book was written that we are given an account of abdominal hysterectomy while the vaginal operation is not described. The author expresses himself as very sceptical in regard to deaths after the third day in this operation which are put down to shock or exhaustion; he considers that in all probability they are the result of sepsis. Chapters on Extra-uterine Fœtation and Peritonitis follow. In the account of Gastrostomy Mr. Cripps declares that he sees no necessity for the elaborate operations which have been devised in recent years, for he finds no difficulty in preventing the escape of gastric juice by using a small pad which he has invented. It consists of a flat rubber disc a little larger than the opening into the stomach; it is pierced by a double thread and is introduced into the stomach by being rolled up. When it is desired to close the gastrostomy opening this is drawn forwards and the threads are tied over a little roll of lint containing a glass rod.

The author advises an operation in appendicitis even after the first attack if a persistent swelling can be felt in the iliac region, and in all cases with recurrent attacks. In cases in which the large bowel is obstructed and yet the exact cause cannot be ascertained Mr. Cripps urges that an incision in the left iliac region offers the best chance of ascertaining the cause and, if necessary, of performing a palliative colotomy.

The author appears to be much prejudiced against Murphy's button, but the good results which have undoubtedly been obtained by its use by many operators go far to neutralise the argument drawn from the 4 fatal cases which Mr. Cripps quotes.

Other chapters deal with Abscess and Hydatids of the Liver and with Removal of the Spleen, but space forbids a detailed consideration. Mr. Bruce Clarke contributes a chapter on the Surgery of the Kidney and, very good though the article is, it is impossible to deal adequately with so important a subject in 32 pages. Mr. C. B. Lockwood is responsible for the account of the Radical Cure of Hernia; it is very satisfactory and we would especially praise the diagrams. Mr. Cripps tells us that he has performed nearly 1000 abdominal sections and he has given in an appendix abstracts of the notes of 183 of the most interesting of these; they will serve well to illustrate the descriptions and enforce the teaching contained in the body of the work. We have read the book with pleasure, for it is the frank expression of the individual views of a surgeon whose wide experience must make his opinions worthy of careful consideration even if not always of full acceptance.

Diseases of Women. By E. C. DUDLEY, A.M., M.D. London: Henry Kimpton. Pp. 636, with 422 Illustrations (of which 47 are in Colours) and 2 Coloured Plates. 1898. Royal 8vo. Price 21s. net.

THE output of gynæcological literature in America during the last few years has been very large, and in Dr. Dudley's book we have the latest addition to the already numerous

American text-books upon Diseases of Women. The author has departed with advantage from the usual classification into diseases of regions and has arranged his work upon a pathological basis, the book being divided into five parts as follows: I., General Principles; II., Inflammations; III., Tumours, Malformations, and Tubal Pregnancy; IV., Traumatisms; and V., Displacements and Pelvic Massage. It is of course quite true, as he contends, that dysmenorrhœa, amenorrhœa, menorrhagia, and sterility are symptoms and not diseases, but we doubt whether the fact that there is no collective account of any of these conditions and that we are referred to the index for their consideration will commend the book to students or practitioners seeking information upon these subjects. The result of reading this work is to strengthen the impression that the gynæcologist is becoming daily more and more of a surgeon and less and less of a physician. A very large part of the book is taken up with the account of various operations and in some instances an undue amount of space has been allotted to matters which we, in this country at any rate, are inclined to regard as of rather secondary importance. For example, the description of the operation of trachelorrhaphy occupies some twelve pages while ovariotomy is dismissed in five, two of which are almost entirely occupied by drawings of instruments. There is a similar want of proportion about other parts of the book which detracts from its value, although many of the chapters are excellent not only in the matter they contain but also in the manner in which it is treated.

The first part of 140 pages is taken up with General Principles, Antiseptic and Aseptic Surgery, and the technique of minor and major operations. This part concludes with a chapter upon the Relation of Dress to the Diseases of Women. The author calls attention to the fact that the average woman wears seventeen layers of dress material round her waist constituting if joined end to end a bandage 34 ft. long. In the hygienic form of dress which he advocates these seventeen layers would be reduced to five, but we doubt whether it is of any use to attempt to convince the average woman in a matter of this kind subject as she is to the dictates of fashion. We must confess that we do not regard the illustrations as wholly convincing; for instance, the young woman who is represented in a composite photograph with and without her stays has a much better figure with than without them, an inference which, we gather, the author would not wish us to draw.

Part II., upon Inflammations, is well arranged; the plan of considering salpingitis, ovaritis, and pelvic peritonitis in close proximity to one another is a good one and calculated to impress upon the reader their close etiological relationship. Part III. treats of Tumours, Tubal Pregnancy, and Malformations. The chapters upon Fibroid Tumours and Carcinoma are good and clear, but the account of tubal pregnancy is somewhat disappointing. Part IV. is devoted to Traumatisms. The author expounds his views upon tear of the perineum in some detail, and describes with numerous clear diagrams and figures the operation which he recommends and practises for this condition. Part V. contains an account of Displacements of the Uterus and their Treatment, especially the treatment by operation. Under the treatment of chronic inversion of the uterus we notice that no mention is made of by far the best and most successful mode of treatment—continued elastic pressure with Aveling's repositor, or of the method of performing posterior colpotomy and dilating the constricting ring with the fingers in cases where elastic pressure fails.

The book concludes with a good account of pelvic massage, a mode of treatment which has found little favour in this country. There are some 400 illustrations, many original and others borrowed. Some of these are far from good and it seems a pity at the present day to reproduce figures which give a very poor idea of the conditions which they are intended to represent, such as the picture of a multiple myoma on page 310 or Fig. 172 representing a stage in the operation of myomectomy which is not only a poor drawing but anatomically incorrect. Here and there are some evidences of haste, such as "Cullenworth" for Cullingworth, while Dr. Auvard would hardly recognise either himself or his "Formulaire Gynécologique Illustré" as "Auvard: Illustrated. Falle aus der Frauen Praxis." Dr. Dudley's book has many points of merit but we doubt whether in its present form it will find any permanent place in the gynæcological literature of this country.

A Manual of Otology. By GORHAM BACON, A.B., M.D., Professor of Otology in Cornell University Medical College, New York; Aural Surgeon, New York Eye and and Ear Infirmary. With an Introductory Chapter by CLARENCE JOHN BLAKE, M.D., Profesor of Otology in Harvard University. London: Henry Kimpton. 1899. Price 9*s*. net.

THIS book of 385 pages is well printed and written, and it forms yet another contribution to the literature of aural diseases. Its size prevents it laying claim to be considered an exhaustive treatise on the subject but it contains much that is good and useful. Due space has hardly been allotted to matters of importance. Thus the treatment of aural exostosis occupies one short paragraph and the description of the treatment of nasal polypi complicating deafness is so brief as to give a novice a very inadequate idea of the difficulties surrounding these cases. The author condemns operations for chronic catarrh, such as excisions of the ossicles, and states truly that no s[illegible]ions can be free from the risk of making patients w[illegible]ey were before. The chapters on Sinus Thro[illegible]ebral Complications of Middle Ear Disease are [illegible] in the book. The index is hardly extensive [illegible] instance, no direct reference is made in it to th[illegible]eign Bodies in the Ear. The work is well [illegible]ough most of the anatomical plates are ta[illegible] Gray's Anatomy.

The Cold Bath Treatment of Typhoid Fever. By F. E. HARE, M.D. London: Macmillan and Co. 1898. Pp. xii and 196. Price 6*s*.

DURING his tenure of the post of resident medical officer of the Brisbane General Hospital the author of this work had ample opportunity for testing the value of therapeutic measures in fever; and on the particular subject of which this volume treats it would be difficult to find what, without disparagement, may be termed a therapeutic experiment carried out on such a scale and under such rigid conditions as obtained in this instance. The introduction of hydrotherapy into the treatment of fever dates from the time of Currie, but it was left for Brand of Stettin to advocate the systematic use of cold baths in typhoid fever upon very definite and well-reasoned grounds. His main argument was that early recourse to this treatment robbed typhoid fever of much of its dangers, influencing even the character of the specific disease; and although others who have followed the practice may not have admitted so much there has been a general consensus as to the benefit derived from the measure in subduing the intensity of the febrile process, the long-continued duration of which is one of the gravest risks which the subject of typhoid fever encounters. The method of the application of the bath, the rules for its employment, the frequency with which it is necessary to apply it, and the contra-indications that prevent recourse to it—these and every other subject cognate to the treatment are fully and clearly stated by Dr. Hare whose results are worthy of the most attentive study. It is impossible to read his experiences without being convinced of the efficacy of the treatment and that not merely in the lessened mortality which he proves to follow its employment but from the striking manner in which most of the more serious symptoms are controlled. The work is all the more valuable because it affords a comparison between series of cases in which the treatment was purely expectant and another series in which cold bathing was systematically followed. The numbers too are large enough to satisfy the most captious of critics and we have no doubt that the publication of this book will lend an impetus to the more systematic adoption of the practice in our fever hospitals We do not think any useful purpose will be served by culling statistics from the volume before us The book should be thoroughly and carefully perused by all who have the charge of fever patients It might be urged that alternative antipyretic measures receive but little notice, but we venture to think that no such measure has been proved to be so efficacious as that of which this volume treats

---

JOURNALS,

The *Practitioner* for January appears in an enlarged form The Editorial Month includes among other interesting matter a striking statistical diagram showing death rates from small pox in Prussia Holland, and Austria In the two former countries comparisons are shown between the years when compulsory vaccination did not exist and those in which it did In Austria compulsory vaccination does not exist, and the small pox death rate is marked In the original articles Professor Clifford Allbutt contributes an admirably written article on Tuberculosis Mr Treves recounts an interesting case of Jaundice of sixteen years' standing treated by operation, and Mr Edmund Owen has a useful paper upon Conical Stumps The Hero of Medicine is William Hunter and the Medico Literary Causerie deals with "Doctor Therne"

Die Therapie der Gegenwart Edited by Professor G. KLEMPERER Berlin —This journal first appeared forty years ago, but this year, owing to the resignation through ill health of the former editor, Professor Löbisch, it enters on a new phase of existence under the guidance of Professor G. Klemperer It is intended to deal primarily with practical therapeutics, but it will also contain articles and abstracts on closely allied subjects, such as experimental therapy The editor is to be congratulated on the contributors whom he has obtained for the first number of the new series Professor Virchow writes on General Therapeutics, Professor E von Leyden on Nourishment in Acute Fevers; Professor Senator contributes Remarks on the Hygienic and Dietetic Treatment of Chronic Diseases of the Kidney, with especial reference to Climatic Treatment, Professor Schrotter furnishes a paper on the Therapeutics of Arterio-sclerosis, Professor A Fränkel writes on the Treatment of Pneumonia with Large Doses of Digitalis and Professor Eulenburg on the Work Cure (*Arbeitskuren*) in Nervous Diseases In addition abstracts are given from various publications

The Journal of Physiology Edited by MICHAEL FOSTER, F R S, and J. N LANGLEY, F R S Vol XXIII No 4, Nov 25th, 1898, price 5s, and No 5 Dec 30th, 1898, price 4s —The contents of these numbers are as follows —In No 4 1 Dr F Gowland Hopkins and Mr W B Hope of Guy's Hospital on the Relation of Uric Acid Excretion to Diet, with 10 figures 2 J H Elliott, M B, of Toronto on a New Proteid Reaction This consists in the application of dilute sulphuric acid to proteids which stains them of a blue violet colour when allowed to concentrate slowly 3 Dr Harry Campbell on the Resistance to the Blood Flow 4 Professor E A Schäfer on the Alleged Sensory Functions of the Motor Cortex Cerebri 5 Dr William J Smith Jerome on the Relation of the Degree of Acidity of the Urine and the Percentage of Uric Acid therein contained to the Precipitation of the Latter in the Form of Uric Acid Gravel 6 Professor J Burdon Sanderson the Electrical Response to Stimulation of Muscle, being the second part of the essay on the Monophasic and Diphasic Variation of the Sartorius, with a plate and eleven figures in the text The first article in No 5 of the Journal is by W B Hardy, M A, of Caius College, entitled Further Observations upon the Action of the Oxyphil and Hyaline Cells of Frog Lymph upon Bacilli, with ten figures in the text 2 Dr Ralph Stockman and Dr E D W Greig on the Action of Arsenic on the Bone Marrow and Blood, with a plate 3 Dr Charles J Martin on Cortical Localisation in Ornithorhyncus, with four figures in the text. 4 Dr M S Pembrey and Dr B Nicol on Observations upon the Deep and Surface Temperatures of the Human Body, with two figures 5 Dr J N Langley on Inhibitory Fibres in the Vagus for the End of the Œsophagus and the Stomach To this number are appended the Proceedings of the Physiological Society

The Quarterly Journal of Microscopical Science Edited by Professor E RAY LANKESTER, Professor ADAM SEDGWICK, and Professor W WELDON. New Series, No 163 Vol XLI Part 3 London, J & A Churchill Price 10s —The articles contained in this part are five in number and are as follows 1 The Development of the Pig during the First Ten Days, by Richard Assheton, M A, with four plates 2 The Structure of the Mammalian Gastric Glands, by R R Bensley, B A, M B, of Toronto, with a plate 3 On Certain Green (Chlorophylloid) Pigments in Invertebrates, by Marion Newbigin, D Sc, of Edinburgh, with two plates 4 *Note on a* (Stomatopod?) Metanauplius Larva by J J Lister, M A, of Cambridge 5 On the Nephridia of the Polychæta Part 2 Glycera and Goniada, by Edwin Goodrich, B A, of Oxford, with four plates

The Grant Medical College Magazine —This is the journal of the Grant Medical College Gymkhana and it reached its second number in December, 1898 The most noteworthy article in the number before us is a supposed case of Moveable Kidney reported by Mr K M Pardhy All the symptoms pointed as surely as symptoms can to an abdominal tumour being a floating kidney, but when an exploratory incision was made for the purpose of fixing the kidney if it was floating the kidney was found in its proper place and the tumour turned out to be a portion of the ileum affected with tuberculous ulceration Mr B R Khandekar reports a case of Tetanoid Spasms in a woman, aged twenty three years due to intestinal worms

THE VACCINATION ACT —The Kingsbridge (Devon) Board of Guardians at their meeting on Dec 31st decided to support the petition to Parliament for the repeal of the new Vaccination Act —The Cirencester Board of Guardians have passed a resolution protesting against the new Vaccination Act —The Bedminster (Bristol) Board of Guardians at their meeting held on Jan 3rd decided to petition Parliament to repeal the new Vaccination Act —The Pontypridd Board of Guardians at their meeting on Jan 4th decided to petition Parliament to repeal the new Vaccination Act

THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST —Sir Squire Bancroft with a view to helping the Royal Hospital for Diseases of the Chest, City road, in its work, has promised to tell the story as arranged by himself from the author's text of Charles Dickens's "Christmas Carol" at the St. George's Hall, Langham place W, on the afternoon of Thursday, Jan 19th Mr Hope Morley, the treasurer of the institution, will preside and tickets, which are 10s, 5s, and 2s 6d each, can be obtained from the secretary.

THE LANCET.

LONDON: SATURDAY, JANUARY 14, 1899.

THE promoters of the Midwives Bill have lost no time in drafting a Bill (now called "A Bill to Promote the Better Training of Midwives and to Regulate their Practice") intended to meet the views of the General Medical Council, as expressed with practical unanimity in the report of the Council at its April meeting of last year, and discussed afterwards at the conference between a committee of the Council and a deputation from the Midwives Bill Committee. This Bill bears on the face of it new features, and comes before the profession and will come before Parliament with a claim to consideration which its predecessors lacked—the claim that it has been shaped more or less to accord with the views of the General Medical Council. We propose to inquire at this stage how far the Bill answers to the new intentions of its framers and is any guarantee that they will endeavour loyally to secure the enactment of those principles which were not embodied in their previous Bills, and the absence of which involved the opposition of the General Medical Council. And the support of the General Medical Council will, we take it, be entirely conditional on this loyalty. The innovations in the Bill must be supported in Parliament by its promoters as of the very essence of the Bill and without which it must not pass. Nor does it follow that because the Bill meets the requirements of the General Medical Council it will be a grateful measure in every detail to the medical profession. It is not the authority of *the General Medical Council that is at stake or, for that* matter, the interests of the medical profession, but the lives of women; and, as we have said on a former occasion, the proposed legislation will lack all justification if it continues to allow an ignorant and perhaps drunken and incompetent woman to hold herself out as a midwife. Such behaviour must be penalised.

The essential views of the General Medical Council as put forward in the report of the Midwives Bill Committee, adopted, were:—

(*a*) That every woman *engaging for gain in practice as a midwife* should be subjected to legal regulation and control.

(*b*) That the mere prohibition of titles without making illegal the practice of midwifery by unauthorised persons was not a sufficient safeguard to lying-in women.

(*c*) That all conditions and regulations framed by a Midwives Board for the Control of Midwives should be submitted to the approval of the General Medical Council and the issue of such conditions and regulations when so approved by the Local Government Board to the local sanitary authorities.

(*d*) That every woman before beginning to practise as a midwife in any district should obtain the licence of the local sanitary authority of the district, renewable annually and revocable any time on infringement of regulations.

(*e*) That any unlicensed woman, whether calling herself a midwife or not, who, not being registered under the Medical Acts, practised as a midwife for gain should be liable to a substantial penalty.

(*f*) That evidences of character, training, and experience should be forthcoming in case of applicants for licences.

(*g*) That licensed midwives should be under obligation (by regulations) to secure immediate qualified medical assistance in every case presenting symptoms of difficulty or abnormality.

Another requirement of the General Medical Council was that direct provision should be made in the Bill to reimburse the Council for any expenditure incurred in duties under the Bill. This has been ignored.

These were the principles which, in the opinion of the General Medical Council, should underlie any legislation on the subject of midwives. Their essence is this: that midwifery is a part of medical practice, calling for full knowledge of the principles of medicine and surgery—that there must be a clear recognition of the distinction between a mere midwife and the medical practitioner and that she is to act in midwifery an entirely subordinate part, with sharp limitations to be defined in the regulations; and that any violation of the regulations will render her liable to removal from the roll of midwives.

How far does the new Bill embody these principles and secure their recognition in the future? On the whole the Bill meets the requirements of the Council. Existing midwives will be required to show not only that they have attended cases but to produce evidence of character and of being in *bonâ fide* practice as midwives. Mrs. GAMP was in *bonâ fide* practice, but the necessity of adducing witnesses to character would exclude her from the new roll. The Council, however, asked for evidence of training also, but the Bill does not provide for this. Secondly, obstetric assistance may be rendered by anyone in an emergency, but the habitual practice for gain of midwifery by an unlicensed woman not a registered medical practitioner will expose the offending person to a fine of not more than £5, as the false use of titles also will. Thirdly and fourthly, licensing is substituted for registration, renewable annually, and besides the licence of the Midwives Board a midwife must get a certificate from the local sanitary authority in whose area she means to practise. The constitution of the Board is altered for the better. The Midwives Board of this Bill will consist of only 6 members, of 4 registered medical practitioners appointed respectively by the Royal College of Physicians of London, the Royal College of Surgeons of England, the Society of Apothecaries, and the Incorporated Midwives' Institute, and 2 other members to be appointed by the Privy Council. The claim of the body which has no professional knowledge to have as much representation on the Midwives Board as the medical corporations is one to which we demur, however it is all for good that the Board should be so much smaller. It will be at least predominantly a medical body and its regulations will be subject to the approval of the General Medical Council. We cannot, however, regard it as satisfactory that so much is left to the discretion of the Midwives Board. Such vital matters as the distinction between the functions of a midwife and those of a medical man, the obligation of a midwife to send for a medical man on the occurrence of anything unusual, and the obligation of the local sanitary authority to make such arrangements as will secure the ready help of a registered practitioner should be, and we hope still will be, matters of direct provision in the Bill. The opportunity of the presence of such a Bill in Parliament should not be lost also in another direction. A specific clause to make it illegal for a midwife to certify still-births should be inserted. The promoters of the Bill anticipate that the modifications introduced to meet the views of the General Medical Council will excite much opposition both in and out of Parliament. It may be so, but we trust that the Government will refuse to be any party to a Bill which does not include these modifications. There will be other opportunities of discussing the Bill more in detail which we shall take as they arise.

◆

THE reports which have reached us of the severe epidemic of influenza now raging in New York and the undoubted existence of outbreaks of "*febrile catarrh*" (to use a term sometimes employed) now attacking whole families simultaneously in this country have again drawn attention to the nature and means of extension of this disease. Influenza, although in itself not usually a serious complaint, yet in virtue of its complications and sequelæ may prove a most disastrous one and not unnaturally the prospect of another pandemic such as occurred in 1889 and 1890, or of further local epidemics such as have since been experienced, gives rise to no little popular alarm. The name "influenza" seems to have a strong attraction for some people. Every ache and pain, no matter where located and whether accompanied by fever or not, is at once put down as "influenza"; every headache, every coryza, every sore-throat, every attack of gastro-enteritis, from whatever cause is promptly self-diagnosed as "influenza," and when the practitioner arrives upon the scene he will be expected to fall in with this view, and there is a great temptation to do so. The disease is so protean in its forms that it is no cause for surprise that the patient arrives at the above conclusion. A little investigation, however, may show that many of the so-called "gastric cases" can be ascribed to errors in diet, whilst the general history of other cases would indicate that similar attacks of headache, sore-throat, or coryza have occurred at intervals throughout the patient's whole lifetime, at any rate many years previously to 1889, at which time the modern history of this complaint as regards England begins. A certain number of cases characterised by rise of temperature with some amount of general malaise are frequently met with and were encountered long prior to 1889, but there is no evidence that these are influenzal in nature. For want of a better term the condition is described in text-books as "febricula"; the symptoms disappear in a few days and the patient recovers. At the same time such maladies should be carefully watched in case they should be mild cases of influenza and evidences of complications should be at once investigated.

The publication of the fifteenth volume of the "Twentieth Century Practice of Medicine" comes opportunely for it contains a most valuable article on Influenza by Dr. DITMAR FINKLER. The article forms, indeed, one of the best monographs on influenza which we have yet met with. In reference to the remarks which we have already made we quote the following from Dr. FINKLER'S observations on "Local Epidemics." "I am inclined to accept the view of LEICHTENSTERN that there exists a pandemic influence caused by PFEIFFER'S bacillus and also an epidemico-endemic influenza of identical nature, which develops after the pandemic infection has run its course, being caused by the germs left by the latter. ..... The occurrence of various forms of catarrhal fever, which are often called grippe or influenza by physicians and laymen, is something altogether different. Sporadic cases of coryza and bronchial catarrh should never be mistaken for influenza, although the symptoms of influenza may here be imitated in an exquisite manner. I have examined whole series of such cases, but have never been able in a single instance to demonstrate PFEIFFER'S influenza bacillus."

The question, then, arises—Can the diagnosis of influenza be based on the microscopical finding alone of the influenza bacilli? Dr. FINKLER maintains that under certain conditions this question may be answered affirmatively and he states that anyone who has occupied himself largely with these bacilli will rarely err when he sees them in a sputum preparation. He adds, however, that it is most desirable to establish the identity of the bacilli by culture if every doubt is to be excluded, for this method leads to the certain demonstration of the influenza bacilli often more rapidly than does the microscopical examination. According to these investigations doubtful cases of influenza should not be diagnosed as such unless a bacteriological examination has demonstrated the presence of PFEIFFER'S bacillus, following the plan now uniformly adopted in uncertain cases of pulmonary tuberculosis and diphtheria. Such a course would prevent the indiscriminate diagnoses now occasionally made according to the particular physician's own ideas of influenza rather than by the recognition of a disease having definite characteristics. We have not been able to discover in Dr. FINKLER'S paper any mention of an apyrexial form of the disease, and we believe such cases to be extremely rare even if they exist at all. We are aware that in the opinion of some physicians they do occur but we are not aware of the grounds upon which the statement is made, nor should we be satisfied with the reasons unless a bacteriological examination had corroborated the diagnosis.

◆

ANY article by Professor J. P. MAHAFFY is pretty sure to be worth reading. We may not always agree with him or think his tone particularly judicial; but he is always pithy and piquant, he has something to say that is individual and characteristic, and he speaks his mind with an undeniable frankness. All these qualities are conspicuous in his article in the *Nineteenth Century* upon "How to Prevent Cramming." He refers more specifically to Irish secondary education, but his remarks have a wider application than their immediate object and may not be without a certain suggestiveness in relation to the teaching of medicine.

What is cramming? It may be roughly defined as the art of preparing candidates to pass their examinations successfully without having really assimilated the knowledge imparted to them and made it a permanent part of their intellectual life. The teacher trains, the crammer imparts information which will pay in the examination room. As Professor MAHAFFY says, "The teacher makes the permanent improvement and development of his pupil the real end or object of his work, in aid of which competitions, prize lists, and exhibitions are merely a test and a means. The crammer makes the prize list his real end and the pupil only the means whereby he may attain honour, money, success for himself, and if he can show a splendid list of examination successes he cares not what becomes of his pupils in after-life. He has done his best with them so long as they were preparing for a special examination. He has played the game of competition and has won. He is not concerned about the rest." This is a somewhat extreme statement of the case, and we would prefer to believe that the average crammer retains some small modicum of the *milk of human kindness* and is not absolutely indifferent to the future welfare of his pupils. But his radical vice is the preferring of immediate gain to real development of intellect and character and of appraising the knowledge not for its inherent worth but just in so far as it can be made to pay. The question at once arises whether examinations properly conducted by able and conscientious men cannot be so arranged as to distinguish between crammed knowledge and real knowledge, between the candidate who has been simply drilled to answer with mechanical accuracy and the candidate who has fully assimilated his materials and adjusted them to his total mental equipment. This is the crucial question upon the answer to which everything depends. "It is impossible to abolish examinations. They are, in the first place, a distinct test, though a rude and insufficient one, of good and bad teaching. In the second place they are the *only* test which the public understands and in which therefore it has confidence. We must therefore not attempt to abolish examinations, but *to reform them* so as to leave good teachers the maximum of liberty, and give weight to quality and not variety of answering." The proper conduct of examinations is one thing and *a most important thing, but Professor* MAHAFFY also lays much stress upon the proper inspection of schools by independent inspectors, entirely removed from local, sectarian, or other jealousies. In the medical world something has been done to secure inspection of examinations, but very little has been done to secure inspection of academic and clinical teaching. We believe that much remains to be accomplished in this regard and that the best results might be fairly expected to follow from proper inspection of the medical student's training on both its sides.

Some of Professor MAHAFFY'S remarks upon the teaching of modern languages have an interest for medical readers, inasmuch as some knowledge of this subject is required for the medical curriculum in most of the universities. "We learn the classical or so-called dead languages for the sake of their matchless literature and for the sake of their logical and strict grammar; we learn the modern for use, for speaking, writing, reading them, and understanding them when spoken. The use of Latin grammar is to learn grammatical principles which can be applied to many languages; the use of German grammar is merely to understand German and no one would think of studying it for *any* other purpose. Hence in the learning of modern languages grammar should take a very subordinate place and *use* should be the object always in view." This is, we believe, true and important. The much-weighted medical student cannot in these days spare time to acquire a thorough grammatical and philological knowledge of French and German. But if he aspires to any career higher than that of ordinary general practice it is most important for him to be able to read these languages with facility. Learning to speak them, though most desirable, is, on the whole, a secondary matter. It is not everyone who travels; and even in the case of travellers it is astonishing to find the extent to which English has become a sort of *lingua franca* upon the Continent and how little real inconvenience is felt by many who travel with the command of no language but their own. No doubt this is to be deprecated and is something of a slur upon anyone who has had a liberal education, but our point is that for practical purposes what the aspiring medical student needs in this department is *simply* the power to read French and German with ease and readiness, so that the very important medical literatures of those countries may be accessible to him without the aid of translations. Upon the whole, we conceive that medical education is much less open to the charge of cramming than that of most other departments. Some of the subjects can hardly by any possibility be crammed. We once knew a very clever student who detested dissecting and who yet contrived to pass brilliantly in anatomy by means of *an* elaborate system of mnemonics devised by himself; but we imagine such cases are excessively rare. To cram clinical knowledge is almost a contradiction in terms. The stress now *thrown* upon practical laboratory work, the tendency to discourage systematic lectures and to rely more upon bedside teaching, the discrediting of mere book knowledge,—all this tends to the confounding of the medical crammer. Examining students in mere "tips," attaching importance to names rather than things, allowing the opinions of examiners—as opposed to recognised scientific doctrine—to have full play,—these things still find a place at some medical schools, and create a function for the crammer, but it cannot be too much insisted upon that *such* practices are opposed to all sound principles in medical education and can be persisted in only from ingrained prejudice or deliberate wrong intention.

SINCE we last commented in these columns on the cases of COLLINS and WHITMARSH the sentence of the latter has been fixed by the Home Secretary at penal servitude for twelve years as against the seven years allotted by Mr. Justice GRANTHAM to COLLINS, and the sentence of death passed by Mr. Justice PHILLIMORE in the later case of WARK has now been reduced to one of penal servitude for three years. The term meted out to the last-named criminal seems to fairly satisfy the exigencies of the case. It may seem severe in comparison with the sentence upon COLLINS and so may the fate *of* WHITMARSH, but it must be remembered that the Home Office has its own precedents to follow and cannot allow itself to be influenced by the views of a particular judge in another case than that under its consideration. No one conversant with the practice in such matters can have seriously expected a free pardon to be granted in a case in which a question of fact had been carefully tried before a judge and jury and where no additional evidence has been since adduced. Many of those who have agitated with a view to the immediate release of WARK and have been surprised to find their petitions ungranted must have forgotten the sources of information at the command of a Home Secretary that place him in command of particulars which are not made public in a court of law but which rightly influence his decision. Many, too, must have failed to consider how important it is that the verdict of a man's twelve peers, even if adverse to him, should not be overridden by the opinion of any official however highly placed, unless, as we have said, the official has evidence before him that was not before the jury tending to prove innocence. It seems to us that so far from the Home Office being called upon to exercise its powers more markedly than it has done far too much is now expected from it and done by it in such cases as these.

In this connexion we note that it was at Liverpool, where the WARK case was heard, that the last trial took place in which the sentence of death passed upon a criminal abortionist in England was carried out. This was in 1875, the man being an unqualified practitioner of the name of HEAP. The late Baron POLLOCK tried the case and he expressly said that the facts, if proved, constituted murder and nothing else, while the law has, we believe, been similarly laid down in all cases of the same nature until the present year. On its being found that HEAP was to be hanged efforts were made to obtain a reprieve, and the foreman of the jury who had recommended him to mercy made a public statement that had the jury known that the capital sentence would be carried out they would have found a verdict of manslaughter. The judge, however, had held out no hope of mercy, there was a previous conviction for abortion against HEAP, and the Home Office was inexorable. In the years following the case of the man HEAP there were convictions for similar crimes (there had been none for some time before that case)—that of CORNELIUS ASHER, a herbalist at Leicester, in 1876; that of ANN CARTLEDGE, a midwife, in 1877; another of a woman in 1879; *two* separate cases in 1880 (the two COLMERS and an unqualified practitioner named HAYWOOD), and the case of a chemist named HOLLIS in 1882,—in all of which reprieves followed. In all of these cases, in spite of the recent precedent of HEAP'S case, the death sentence was not carried out and in them, and in all such cases since, the Home Secretary, and not the judge who tried the case, has fixed the penalty for the crime. This crime has been, technically, murder, the jury only convicting because ignorant that a death sentence would be passed or expecting confidently its commutation. The difficulty of persuading the jury of even the technical guilt of murder on the part of the prisoner is shown by the way in which the law has been laid down in the three recent instances already referred to. According to the Attorney-General in the COLLINS case (and apparently the judge took the same view), "if the act done was not in itself of necessity dangerous then the jury might find a verdict of manslaughter and not murder." According to Mr. Justice BIGHAM in the WHITMARSH case, "If the jury could bring themselves to think—he did not see how they could—that though the prisoner might have administered the injection yet nevertheless as a reasonable man he could not have contemplated that it would result in death, it was competent for them to say that he was not guilty of murder but that he was guilty of the lesser crime of manslaughter." According to Mr. Justice PHILLIMORE in the WARK case "if a person committed any felony on the body of anyone to whom thereby death resulted he was guilty of murdering that person."[1] It is in consequence of such conflicting and irreconcilable enunciations of the law that we have urged the desirability of legislation with regard to cases of what is sometimes known as "constructive murder," a convenient term against the use of which Sir FITZJAMES STEPHEN once emphatically protested. Failing this we have suggested the possibility of a uniform practice of indicting for manslaughter, except perhaps in such exceptionally heinous cases as may possibly arise. The object of such legislation or practice would be to produce consistency and prevent the possibility of a criminal being acquitted through sympathy or prejudice. It is quite another matter to urge that a jury's verdict should be rendered wholly ineffective where it simply amounts to a finding that whatever crime the acts committed involve the prisoner was privy to it. To do this would be highly undesirable, even if the judge trying the case admittedly assumed a responsibility in directing the jury from which some of his colleagues would have shrunk.

Annotations.

"Ne quid nimis."

BRITISH ACTION AS TO PLAGUE

WE are glad to be able to announce that the action taken by the British Administrator of our East African *possessions* was suspended on Jan. 8th and this we may assume means that it was cancelled. The mere fact that the governor of a British possession should repulse a vessel on which there existed an infectious disease such as plague and order her out to sea to return to the port whence she came, without so much as seeing that over 1000 people on board should run no further risk of infection and should not remain a single day without ample medical appliances and *provisions*, was an act which we did not hesitate to style "astounding." Even if all these precautions could possibly have been taken the action would have been wrong in principle and thoroughly bad in practice; and the only plea in extenuation of having acted thus in a state of panic would be that which should properly be regarded as inexcusable—namely, an utter neglect of measures of preparation in the case of a port which for over twelve months has been in constant communication with plague-infected ports of India. The final decision with regard to the *Bhundara* is not yet made known, but we learn from Karachi that there has for many days past been no further case of plague on board. Hence such elementary sanitary organisation as must surely exist in a country which is constantly shipping railway employés from Karachi and Bombay, and where large works under British supervision are being carried on, ought to suffice to control a disease which has for two years been kept from spreading from the native to the British quarters of even a great city such as Bombay. The Venice Convention lays it down that no country accepting its provisions shall be without a port organised to carry out the terms of the convention. This means that no such country shall have even the excuse for repelling a vessel, and this country cannot afford, even in East Africa, to revert to an attitude of a past generation which was characterised by ignorance as to the meaning and significance of infectious disease.

---

[1] We quote the dicta of the *Attorney-General* and of Mr. Justice Bigham from the *Times* reports of these cases, while the words of Mr. Justice Phillimore are as given in the *Liverpool Daily Post*.

THE CENTENARY FESTIVAL AT ST. PETERSBURG.

THE brief account of the centenary of the Military Medical Academy given in an annotation in THE LANCET of Jan. 7th extended to the ceremony of Dec. 30th, 1898, at which the congratulatory addresses of the delegates were presented. On the evening of that day a ball was given and some of the delegates afterwards drove down the Neva in troikas to spend the very early hours of Saturday morning (Dec. 31st) in a well-known and popular cave of harmony. On the same day at mid-day an opera (*Le Prince Igor*) was given to a crowded audience at the Imperial Theatre. An interesting feature of this performance was that the opera was composed by Dr. Borodine, a late professor at the Medical Academy. In the evening a banquet was given. At this splendid entertainment the French delegates were to the right of the President, the Germans to the left, the British representatives being opposite to them. On Sunday (Jan. 1st, 1899) a visit was paid to the large non-military hospital associated with the Imperial Academy and to the Physical Laboratory over which the delegates were shown by the kindly Dr. Danilevsky who showed many experiments with liquid air and demonstrated an extremely clever apparatus by Zeiss by means of which images of small opaque bodies could be perfectly reproduced upon the lecturer's blackboard or screen. The chief part of Monday was spent in a tour of inspection through the immense establishment on the islands at which all the instruments, splints, dressings, and apparatus are made for the army. This was followed by a luncheon at which speeches of congratulation were made. The chair was occupied by Dr. Remmert, the chief inspector of the imperial army. On Wednesday, Jan. 4th, a miniature review was held by the Czar in an enormous riding school, and on its conclusion the delegates had the great honour of being presented one by one to his Imperial Majesty. Some of the French delegates whose return from a hurried visit to Moscow was delayed by a snowdrift were so unfortunate as to miss this important part of the proceedings. But all the British representatives were there—Rev. H. S. Cronin, Mr. Cross, Dr. Ferguson, Professor Ogston, Mr. Owen, and Professor Shipley. Throughout the entire series of functions the Minister of War showed by his presence that he deemed the Army Medical Department of real importance to his country. He expressed considerable pleasure at receiving congratulatory remarks from his visitors. It evidently gave him particular satisfaction to read out at the banquet before 500 guests a congratulatory telegram which arrived from the German Emperor. Amongst the Russians who specially endeavoured—and that with great success—to render the visit of the British delegates successful and pleasant may be mentioned Dr. Alexis Likhatscheff, Mr. Berthenson, Mr. Sellheim, Professor H. Turner, Mr. Wyllie, Dr. Slifosoffski, and the Medical Superintendent of the Hospital of the Academy. Greatly to the regret of every one, Russian and foreign, the President of the Academy, Dr. Pachoutine, was laid up by a severe attack of influenza. He may, however, be sincerely congratulated on the perfect way in which his arrangements were made and carried out and upon the great pleasure and enjoyment which he ensured for his foreign guests. It is to be hoped that now the festival is so successfully ended he may find the opportunity of taking needful rest and of completing a perfect convalescence. The delegates begged leave to offer him "a very happy new year" which, according to the Russian style, began on the 12th of this month.

THE USE OF THE CAT.

WE have received some publications from the Humanitarian League all pointing out how inhuman it is to flog ruffians who assault and batter passers-by in the streets. Flogging is objected to because it degrades the criminal and also the community by whose will the flogging is inflicted. We do not for one moment accept either of these arguments. The average rough cannot be degraded, although he has a very wholesome regard for his skin. We append a report from the daily press of a case tried on Jan. 5th at Marylebone Police Court in which two Kilburn ruffians were charged with assault. The evidence was as follows: "It appeared that about twelve months ago the prosecutor and the younger prisoner had a dispute. Between 7 and 8 o'clock on Boxing Night the former was walking home by himself along the Lonsdale-road and was turning a dark corner when he was suddenly set upon by six or more rough-looking fellows, including the prisoners, all of whom grossly maltreated him. The prisoners, who were evidently the ringleaders, pummelled him savagely about the face, after which he was felled to the ground by a violent blow in the eye and while still on the ground the elder prisoner kicked him in the mouth, loosening all his front teeth, and the younger kicked him about the legs. In the end he was rendered unconscious and upon coming to he found all the men had disappeared." Now it is to this kind of person, we contend, that a flogging is the most effective punishment. As a matter of fact the prisoners were sentenced to two months' hard labour during which time the country will have to pay for their keep and lodging. Humanity is wasted upon creatures of this sort.

NETLEY AS A SCHOOL FOR TROPICAL MEDICINE.

IN THE LANCET of Dec. 31st, 1898, we drew attention in detail to the advantages that Netley would offer as a school for tropical medicine could the necessary arrangements with the War Office be made. In the *Times* of Jan. 6th is a letter from Dr. John Anderson who obtained permission from the War Office to apply to the principal medical officer at Netley for a return showing the number of cases of tropical disease available at the Royal Victoria Hospital for the instruction of candidates for the Colonial Medical Service. Full statistics were furnished enumerating the number of patients suffering from tropical disease who were admitted during the years from 1892 to 1898 (to Nov. 30th) inclusive. The figures show that whilst the clinical material for teaching beri-beri is clearly insufficient (this being naturally due to the fact that Europeans rarely suffer from this disease), the advantages offered in other forms of tropical disease are much greater than in any other hospital in Europe. The number of cases of ague and remittent fever in 1897 were 176 and 25 respectively, and in 1898 were 402 and 83. The advocates of the establishment of the proposed school for tropical medicine at the Branch of the Seamen's Hospital at the Albert Docks have made a *point d'appui* of the fact that during the year ending Nov. 30th last 31 cases of *malaria* were admitted into that hospital. This number should be compared with those quoted above. Again, in THE LANCET of Nov. 19th last we mentioned that in twenty-five years only 50 cases of hepatic abscess had been treated at the Seamen's Hospital, whilst at Netley in 1897 there were 33 instances of this disease, and in 1898 (to Nov. 30th) there were 86 cases of "inflammation of the liver" and 20 of "other hepatic diseases." We may also draw attention to the number of cases of "simple continued fever" and of "Mediterranean fever" which were under treatment. The figures quoted by Dr. Anderson add strong support to our contention that although every assistance should be given by the profession to Mr. Chamberlain's scheme, yet the size of the hospital at the Albert Docks (and we are not forgetting the proposed extension) and the number of tropical cases admitted do not justify the proposed large expenditure. We do not deny that it affords a most valuable additional place of study for medical men preparing to reside abroad; but we do protest against the laying out of large sums of money when there already exists such a well-equipped and in every way suitable establishment as Netley.

PRESERVED GLYCERINATED CALF-LYMPH.

IN another column a correspondent draws attention to the fact that at the present time those who are working at the production of lymph do not fully understand the conditions under which the most active and reliable vaccine lymph is obtained from either the calf or the child. Although this is undoubtedly the case it must not be forgotten that certain general information has been obtained which has all gone in the direction of ensuring the production of a fairly and usually a very reliable lymph which when carefully collected and prepared by glycerination retains its original potency for a considerable period and then loses its active properties but slowly. For example, it is now known that the age of the calf is a somewhat important factor, its state of nutrition and general health are others. Then, as our correspondent points out, the season of the year and the state of the weather exert a marked influence on the lymph obtained. In connexion with these two latter factors, however, it should be borne in mind that the calf, like the child, is very susceptible to "warm weather diarrhœa," to rises of temperature due to slight digestive disturbances or irritation from heat, and it has long been recognised both in England and Germany that these slight derangements have a marked effect on the quality of the lymph collected. Taking all these facts into consideration it would appear then that the preparation of reliable lymph is by no means such a haphazard process as is sometimes maintained. It is suggested that glycerination and bacteriological examinations are superfluous refinements unless we can be sure that the vaccine matter has a certain "strength" to commence with. This we should hold is by no means proved. A clear active vaccine if kept for even a short time may, as has often been pointed out, become quite cloudy, and as this cloudiness becomes more and more marked two things occur which certainly cannot be disassociated—(1) the number of micro-organisms present becomes enormously increased, and (2) the activity of the virus rapidly falls. Glycerination then, in so far as it not only prevents the growth of micro-organisms but actually brings about a diminution in their numbers, conduces to the preservation of the orignal activity of the vaccine lymph and, therefore to the chance of a larger proportion of successful insertions. In regard to our correspondent's assertion that it is impossible to tell from a post-mortem examination of the calf whether the vaccine is likely to be "good" or not we would point out that the animal is not killed with that object. The post-mortem examination is made for the purpose of determining that the animal during life has suffered from no specific infective disease—e.g., tuberculosis—which might, under certain conditions be transmitted through the medium of the lymph. At the same time the fact must not be lost sight of, that slight intestinal or gastric disorders or vascular disturbances—local congestion and the like—should always be carefully looked for and taken into consideration in connexion with the probability of the lymph proving to be of reliable quality or not. As matters stand at present it is evident that opinion is in favour of the use of calf-lymph carefully prepared and collected and treated with from five to eight times its bulk of 40 or 50 per cent. pure glycerine, as against arm-to-arm vaccination, and we believe that as time goes on this opinion will be strengthened.

THE CHURCH MILITANT.

WE are always glad to be able to chronicle instances of prompt and brave action by the clergy in times of plague and sickness. Everyone knows the story of Mompesson, the rector of Eyam, during the plague time in the seventeenth century; of Belzunce, the Bishop of Marseilles, during the great plague in the eighteenth century; and of many of the East-end clergy during the cholera in 1866. These are all instances of devotion and now comes a story from a little Essex village exhibiting the same features. The village is White Roding and the rector is James Edmond Long. A week or two ago he noticed some cases of illness among children and also that the sanitary state of some cottages was very bad. Being a man of action he called upon the owner of the cottages and, together with the district councillor, inspected the back premises of the cottages in question. On Dec. 23rd he drove to Dunmow and hunted up the sanitary inspector who went next day and served notices on the occupiers to abate the nuisance. On Christmas day a child was found to be very ill; on the day after a man succumbed, and altogether there were some 16 cases of undoubted diphtheria. On Jan. 1st the child died and the parents were both very ill as well as the other 5 children. No one would see to them; the rector measured the child for the coffin, got the coffin made, took it to the house, laid the body in with *his own hands*, and then took both coffin and corpse to the rectory where he kept it until a grave had been dug. The father died on the same night. His coffin was placed on a trolley which the rector helped to drag to the graveside. If this is the behaviour of British villagers in a mild epidemic of diphtheria it is fair to ask, How would they behave in a small-pox epidemic? And we shall probably not have to wait long for an answer to this question. The parishoners of White Roding may *congratulate themselves upon the devotion* of their rector, for without his action they would have been in sore straits.

A NEW METHOD OF ENUMERATING THE SUDORIPAROUS GLANDS.

A NEW way of counting the sudoriferous glands in the human subject has been devised by Dr. Eijkmann, of the Dutch Colonial Service, who is stationed in Java. Our description is abbreviated from that of Dr. H. Gros in a recent number of the *Archives de Médecine Navale*. The spot selected for examination having been sedulously washed, with soap and water and still further cleansed by means of, alcohol and ether, an alcoholic solution of fuchsine is poured over it and allowed to dry, the drying process being accelerated by fanning. A sheet of fine white paper is then closely applied and maintained in apposition by an evenly adjusted flannel bandage, great care being taken to avoid creases and folds. On removal after a few minutes the paper will be found thickly studded with red stains, each stain representing the aperture of a sudoriferous gland. The fuchsine has no effect on the parts that keep dry, but wherever the paper has been moistened by a drop of perspiration there will be a mark. A whole series of "proofs" can be "pulled" in this way without any need to renew the fuchsine. In determining the number of glands the system adopted for counting the red corpuscles of the blood may be employed. Dr. Eijkmann has examined the skin of the palm of the hand, the forehead, the sole of the foot, the forearm, the arm, the thigh, the back, the leg, and the anterior surface of the thorax in two Malays and three Europeans. On an average of the whole body he found 160 sweat glands per square centimetre of skin in the former and 162 in the latter; but the distribution varied greatly according to situation, the palm of the hand and the brow being the parts which are most thickly studded. As far as the sudoriparous system is concerned there would therefore seem to be little or no difference between Caucasians and their more dusky brethren, but the number of subjects experimented upon is too small to admit of generalisation and, moreover, sweat glands vary greatly not only in size but also as to their secretory capacity.

A SENSIBLE DISTRICT COUNCIL.

THE Urban District Council of Malvern has through its clerk, Mr. William Lambert, issued the following notice to the medical practitioners in the district:—

"BACTERIOLOGICAL TESTS—SUPPLY OF IMMUNE SERUM.

"I am directed to inform you that the Council will be prepared to pay for the distribution of serum for the treatment of diphtheria and the application of bacteriological tests for the diseases of diphtheria, typhoid fever, and tuberculosis in those cases where the persons are unable to bear such expense themselves. I may remind you that the bacteriological tests in question are carried out at the County Laboratory at the Shirehall. "Yours truly,

"WM. LAMBERT."

The District Council through its medical officer of health provides serum and has appointed a bacteriologist in Worcester to examine and report on disease products for medical practitioners in its district. Malvern is one of the few places in which measles and pertussis are notifiable. These facts show the advantages to a community of *having* a medical man free from the restrictions of practice as chairman of its District Council and working energetically with a medical officer of health for a large area, and also independent of practice, for the public good. Malvern is a well-known and popular health resort. It deserves this reputation evidently not only on account of its natural beauties but also from the energy of its sanitary authorities.

"PULSATION OF THE FOOT" AS A DIAGNOSTIC SIGN.

DR. TATTI of Buenos Ayres has published some researches on the "Pulsation of the Foot," which phenomenon he thinks is calculated to be of service in diagnosis. The term pulsation is applied by him to the slight rhythmical movement of the foot which is observed when one leg is crossed over the other by a person in a sitting posture. Though it can be detected by simple inspection it can hardly be observed adequately for clinical purposes without the aid of an instrument constructed on the same lines as the cardiograph. Dr. Tatti gives a large number of tracings taken in this way, most of them accompanied by simultaneous tracings taken by Dudgeon's sphygmograph from the radial artery. In the normal tracing there is an oblique up-stroke; the apex of the curve is acute or slightly rounded. The down-stroke is also oblique, being straight for about the first third of its length; it then becomes sinuous and more or less horizontal. In elderly persons the apex of the main wave is more rounded and the secondary ones are smaller. In children the main wave is small and the smaller ones, which are three or *four* in number, diminish progressively in size. The application of cold diminishes the main wave. Modifications of the curve are observed in pregnancy, especially when there is œdema of the legs, in cardiac disease, and in various other conditions. It is, however, in arterio-sclerosis that the tracing of the pulsation of the foot appears likely to prove of clinical value. Here in well-marked cases this tracing becomes almost straight. Sometimes when the radial pulse gives little or no indication of the commencement of this condition *Dr. Tatti* believes that important information can be obtained from the "pulsation of the foot." As to the cause of the phenomenon he has satisfied himself that the pulsation depends upon the elasticity of the small arteries and capillaries of the leg, so that in cases where this is permanently (as in arterio-sclerosis) or temporarily (as in vaso-motor spasm caused by cold) interfered with the movements of the foot become less than they are in the normal condition.

TYPHOID FEVER IN THE FRENCH ARMY.

THE soldiers of France, according to the past official medical record of the army, have suffered a good deal from typhoid and other forms of fever, not only on their various military expeditions, but in their colonial garrisons and at their military camps and stations in France. Of late years, however, as we have had occasion to point out from time to time, the official returns issued by the French War Office have shown that very great improvement has taken place in this respect. This has been attributable to the greater care which has been taken to secure a good water-supply for the troops by the use of filters and other water-sterilising expedients, such as Vaillard and Desmaroux's highly ingenious apparatus. It appears that there has recently been a serious outbreak of typhoid fever at Cherbourg and especially among the Marine Infantry regiments quartered there. According to the *Temps* there were recently 300 cases of this fever in the Naval Hospital at Cherbourg and numerous deaths had occurred. The epidemic has prevailed since November and the troops deriving their water-supply from the river known as La Divette have been most severely affected. M. Lockroy, the Minister of Marine, has ordered an official inquiry *into the* subject. We think that on the whole less care is taken in France generally than in this country in regard to the *sources* of water-supply for drinking purposes. The fact, however, is that it is really the best and safest way to spare no pains in order to secure a good source of water-supply free from all risk of contamination and to see that the water is protected against any such contamination throughout its course until it reaches those who drink it.

THE NURSING QUESTION AT THE BULAWAYO MEMORIAL HOSPITAL.

THE Bulawayo newspapers have recently been full of correspondence dealing with the question of the nursing staff at the Memorial Hospital. Shortly the position seems to be as follows. Up to the present the nursing at the hospital has been carried out by a band of Dominican sisters who went up in the time of the Matabele war—i.e., in March, 1896—and who worked with the greatest devotion under very trying circumstances. Devotion and willingness, though both admirable qualities in themselves, especially for hospital nurses, cannot, however, in these days make up for lack of training and this training the sisters do not seem to have possessed. In May, 1897, the new resident surgeon, Dr. F. Arnold, was appointed and found matters in a state of complete chaos. Soon after an energetic secretary was appointed and the pair started each in his own department a crusade of reform. After a long correspondence between the matron *on the one* hand and the surgeon and secretary on the other a subcommittee was *appointed* to go into the whole question of management and it was on the report of this committee that the newspaper correspondence started. This report, dated November, 1897, stated that it was agreed to accept the proffered resignation of the secretary and surgeon. The resident *surgeon was, however, asked to remain for* twelve months which he agreed to do. The report proceeded to recommend that a matron and seven trained sisters should be obtained. The position at the present moment seems to be that the resident surgeon has resigned but is remaining and also that the matron and sisters have resigned but are also remaining. The hospital board sub-committee suggested that three of the present staff should proceed to Europe at their own expense to be trained and that to supply their place a matron and three nurses should be obtained from Europe and that their expenses should be paid by the hospital board. However, this scheme fell through and the position remains as we have stated above.

VACCINATION LITERATURE.

WE publish in another column a letter from the energetic secretary of the Jenner Society, pointing out how much good members of our profession may do in educating the ignorant with regard to the value of vaccination. Dr. Bond encloses some of the literature to which he refers in his letter. Perhaps the most convincing pamphlet, if anything but an attack of small-pox can convince a hardened anti-vaccinationist, is one giving a reproduction of two pages of a parish register—namely, that of the parish chapel at Pudsey, Yorkshire, in the years 1781 and 1792. There are 58 burials registered on these two pages and of these the cause of death is given in 34 cases as "small-pox." All the deaths from this cause occurred in patients under ten years of age and most of them were under six years, so that this very well shows how fatal small-pox was in the last century and how it was specially incident upon children. The pamphlet in question is illustrated by a reproduction of a photograph taken in the year 1893 of two cases of small-pox treated in the Birmingham Hospital. The one, that of a child of eleven years vaccinated in infancy, shows only a few pustules on the backs of the hands; the other, that of an unvaccinated child of three and a half years, shows the face covered with a confluent eruption. The latter child died. Probably not even an attack of small-pox would convince a conscientious objector of the type of person who argued that if it were necessary for the child to be inoculated "by beast" the Creator would have done it *before* the child was born; but anyone not absolutely fatuous could not look on this picture without at any rate being given cause for consideration.

"KYNOMANIA."

DR. W. B. MACDERMOTT of Newry sends us a communication headed "Kynomania" dealing with the subject of dangerous dogs and the want of responsibility evinced by the owners of such animals. Without going so far as to agree with the theory which Dr. Macdermott puts forward—namely, that the owner of a dangerous dog is a dangerous or mad man—we quite coincide in his opinion that the number of dangerous dogs in this country is far too great and also that the owners of such animals do not show that contrition for the deeds of their pets which they should. In our opinion the state of the law as regards dangerous dogs wants altering. We believe that no dog can be considered dangerous and its owner punished should it bite anyone unless it can be proved that the dog has bitten someone previously. The position of allowing a free bite is to our minds wholly illogical and we also think that owners of dangerous dogs should be punished much more heavily than they are when they take no pains to keep such animals under control. Dr. Macdermott points out that it is common for boys to set dogs at strangers, "a practice which is leniently ascribed to thoughtlessness but is in reality to gratify an impulse to mischief which when pronounced and developed under absence of restraint is an insane impulse." This, it seems to us, is a *petitio principii* unless we may argue that all unrestrained impulses are insane, as perhaps we may do. The "soaring human boy" is as a rule in the mental condition of a savage but is not prone to develop into insanity as that term is commonly understood. Dr. Macdermott concludes: "To meet offences committed by dogs their owners' responsibility should not be left to be enforced by private initiative but be a matter for immediate police cognisance directed to teach sane responsibility."

DEATH BY ELECTRIC SHOCK, COAL-GAS POISONING, AND A DANGEROUS PRACTICE IN CONNEXION WITH PUBLIC SEWERS.

PUBLIC service supplies are not without their dangers, be the supply water, electricity, or gas. All three have been known to be concerned in bringing an explosion about under the pavements of our streets. Thus leakage from the water-mains may destroy the insulation of electric cables and sparking may result which would ignite any coal-gas which may be escaping from the gas-mains. Sewers also may contain an explosive mixture which should it be ignited by any means would probably rupture the pipe besides being a source of danger to those who examine the working of the sewerage systems from time to time. Only recently three noteworthy occurrences were reported in connexion with gas, electricity, and sewer services which are worth recording although they do not relate to the combination of circumstances to which we have just referred. The first case is that of the death of a man from electric shock at Southampton during the laying of a cable. It appears that a leakage was suspected in a low-tension cable which was lying side by side with a high-tension cable. On proceeding to make an examination, the discharge of sparks having been previously noticed, the poor fellow by some means, though a skilled artisan and well aware of the danger of touching a bare high-tension cable, undoubtedly received a shock which proved fatal. Apparently the deceased had ignored the warning to wear gloves. From the evidence at the inquest it appeared that shutting off the current would have put the town to great inconvenience and it was stated that by exercising great care even high-tension cables could be repaired when "*alive*." The repairing of low-tension cables was not attended with anything like the same risk. The jury returned a verdict of "Accidental death." Considering the poisonous nature of coal-gas, which is due in a great measure to the carbon monoxide which it contains as well as to certain obscure aromatic bodies, it is remarkable that a greater number of cases of poisoning from this cause are not recorded. At a certain dwelling-house in Woolwich last week it was observed one morning that the blinds remained down, and that there were other signs of stillness in the house which implied that something was wrong. On gaining access to the house from the back the police found the rooms pervaded with coal-gas. On reaching the bedrooms the smell of gas was almost overpowering, and one person was found dead in bed and two nearly so. There is hope, however, that these two may recover. At the inquest on Jan. 9th on the body of the deceased person it was stated that there was a defect in an old form of chandelier in the room beneath the bedroom. We believe that this old form of extending gas-bracket has been responsible for many a disaster. In this form of chandelier there is a water seal and when the water evaporates the dipping pipe may be above the surface of the water, the arrangement thus failing as a seal, the gas escaping freely into the apartment. This is a dangerous appliance and should be done away with, especially as modern appliances are now made with special adjustments for extending their length which require no clumsy contrivance for sealing the gas by water. The last case in connexion with the dangers of public services is that in which a firm of chemical manufacturers was summoned at the instance of the West Ham Corporation for discharging dangerous chemical refuse into a sewer. Evidence was given that to this fact a serious explosion could be attributed, the effects of which in the sewers could be seen for nearly half a mile along the line of the sewer, six or seven manholes being blown off, the contents of the sewers at the same time catching fire. A sample of the sewage taken close by the defendants' works ignited readily when a light was applied, the stuff burning for nearly three minutes and throwing up a flame some 18 in. high. The inflammable character of the discharge was probably due to fiery compounds of the nature of benzine. It is quite evident that this unwarrantable procedure might not only be very dangerous but a source also of creating serious defects in a sewer which might have appalling results on the health of a locality. The magistrate was satisfied that the West Ham Corporation had made out their case and the defendants were fined heavily.

TUBERCULOSIS AT RIO DE JANEIRO.

FROM a recently-published lecture by Dr. Moncorvo of Rio de Janeiro it would appear that although of late years the population of that city has largely increased the mortality from tuberculosis has remained pretty nearly stationary. On the whole, the statistics of the disease are said to compare favourably with those issued by the sanitary authorities in Vienna, Berlin, and Paris, but in instituting comparisons of this nature the influence of climate has to be taken into consideration. Sex apparently does not influence the incidence of tuberculosis in Rio de Janeiro, but contrary to a generally-received opinion white children are more liable to suffer than are their dark-skinned congeners. Hereditary phthisis, according to the lecturer, is far from rare; but contagion is likewise a common cause of the disease, especially in the case of nurslings who are given to crawling over floors which have been contaminated by tuberculous sputa and thus run the risk of conveying the germs to their mouths with their fingers. As regards treatment Dr. Moncorvo is a great believer in the virtues of creosote. Having begun with hesitation lest it should not be tolerated, especially during the heat of the summer, he now thinks himself justified in asserting that this medicament is exceedingly well borne by youthful patients and that in it we possess one of the most efficacious of known remedies against tuberculosis.

THE BACTERIOLOGY OF RUM.

IT might be thought impossible on the face of it that there could be any bacteriology of rum seeing that it contains nearly 75 per cent. of alcohol, but according to the results of a very interesting investigation[1] recently made by Mr. V. H. Veley, M.A., F.R.S., of Oxford University, and his wife there does exist an organism in rum which accounts for an apparent disease to which it is liable at times and which is known in the trade as "faultiness." The cause of this disease has long been unexplained, for it has never occurred to those concerned that it could be due to a microbe, especially as the strength of the spirit is only 25 per cent. short of pure alcohol. The "faultiness" of rum is at once obvious when the spirit is diluted with an equal bulk of water, the diluted liquid either immediately or after some hours becoming cloudy and depositing on longer standing a more or less copious precipitate or showing the presence in greater or less abundance of floating flocculencies. The micrococcus which has been isolated and identified as the cause of "faultiness" is a very interesting organism. It does not, however, appear to be pathogenic or toxic according to the results of inoculating a guinea-pig. Its survival in spirit—that is, in a liquid which has hitherto been considered to be one of the best materials for preserving anatomical specimens—is remarkable. Strictly speaking, however, the organism does not flourish in alcohol but "in its gelatinous envelope, thus living as it were in a state of siege in its own castle through the walls of which it can obtain its necessary supplies of food in the form of sugar while keeping out its enemy alcohol." No definite information has been obtained as to the original habitat of this peculiar micro-organism. The discoverers of this new micro-organism which has caused a great pecuniary loss to manufacturers propose to call it provisionally *Coleothrix methystes*, from κολεός (a sheath) and *μεθυστής* (a drunkard)—a name ingeniously suggested by a Fellow of Corpus Christi College.

MORGAGNI AND THE MEDICAL BROTHERHOOD.

IN scientific medicine Italy was England's "first love." The fact is beautifully illustrated by the Italian historian of the healing art, Francesco Puccinotti. He describes for us the great teacher Acquapendente who having dismissed his class for the day with a peroration of noble Latinity is in the act of receiving William Harvey who has just entered the anatomical theatre with Galileo arm-in-arm. While the two elderly Italians are discussing the new inductive method the young Englishman's eye is arrested by a representation of the semilunar valves which Acquapendente has been demonstrating and the future discoverer of the circulation is all aglow with the "trepida gioia" of a pioneer who has just alighted on an "indication" which converts surmise into conviction. Is there no artist, exclaims Puccinotti, to transfer the epoch-making episode to canvas? Another great Paduan teacher who first disclosed to anatomists the coraco-brachial muscle, Casserio, received the thanks of his British pupils in the immortal elegiacs of the "Caledonian Ovid," Arthur Johnston, whose noble rehabilitation by Sir W. D. Geddes is one of the latest and not the least distinctions of the Aberdeen school. The mighty impulse Italian teaching gave to British medicine in the seventeenth century still survived in the eighteenth when the "Father of Pathology" by his writings, if not by his prælections, inspired the Heberdens, the Hunters, and the Baillies of these islands with some of their most pregnant and prolific ideas. Since then, indeed, the pupil has excelled the master and it is Italy's turn to show her gratitude to the successor on whom her mantle has greatly fallen for the restitution to her, with interest, of the "talents" which she sent forth to develop and to fructify three centuries ago. She is steadfastly loyal to the mighty prophylactic of Jenner and proportionately grateful to its deviser. She places on the façade of the surgical wing of her Roman Policlinico the sculptured presence of the pioneer of antisepsis, Lister. She vies with her continental sisters in eliciting and in illustrating "facts for Darwin," and she wins the prize of our Royal Society by Grassi's brilliant work in that field. *Spirat adhuc amor!* and on Sunday last in one of the greatest and historically most distinguished of her clinical schools, the Ospedale Maggiore of Milan, she unveiled and bade God-speed to its London destination the bust of her own Morgagni, glad to be reminded of what Great Britain owes to her in the past. All this is as it should be. In the vicissitudes of evolution peoples and schools have each their turn and none can ever claim to have been independent of its precursors or to have said the last word in the inductive sphere. Medicine, of all other arts the most progressive, the most responsive to every impulse or inspiration from that world with which it keeps in ever more intimate touch, relies most on combination, on concerted movement, on unity of "objective." Such is the strategy, such are the tactics, by which it will gain fresh victories in its perennial conflict with disease and premature death. Conspicuous among contemporary interests for the "brotherhood" it equally requires and maintains, it is yearly contracting new alliances and forming new connexions in furtherance of that most "imperial" of all policies—the humanitarian. It is in this light that we welcome every *rapprochement* between our continental brethren and ourselves, all the more when, as in the case of this latest token of Italian reciprocity and goodwill, it comes from a power to which we may yet owe in the future as much as we have owed to it in the unforgotten past.

---

THE PHARMACEUTICAL SOCIETY AND THE SALE OF POISONS.

THE Pharmaceutical Society of Great Britain held a meeting on Wednesday in Bloomsbury-square for the purpose of discussing new legal regulations with regard to the storage and dispensing of poisons and especially with regard to the prevention of the indiscriminate sale of poisons. Mr. Walter Hills, President of the Pharmaceutical Society, presided. Mr. Robinson, L.C.C., suggested the following resolutions to the members of the society:—

1. That every vessel should be strictly labelled with the particular poison it contained.

2. That poisons in storage should be distinguishable by shape of bottle or package.

3. That in the dispensing and selling of poisons all liniments, embrocations, and lotions containing poisons should be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, and that there should also be affixed to each such bottle a label giving notice that the contents of the bottle are not to be taken internally, in addition to the name of the article and any particular instructions as to the use.

After considerable discussion the resolutions were carried by a vote of 111 to 5.

THE CHARGE AGAINST DR. REICHARDT.

THE case recently heard at the Surrey Quarter Sessions at Kingston has naturally aroused much interest amongst medical men. The care of patients of weak intellect in private houses always gives rise to no little anxiety and it is often very difficult to say whether such a person should be certified or not, for it "must be fully understood that a person of unsound mind can transact business unless he has been placed under certificates, so that a person, although acknowledged by his friends to be a lunatic, can sign cheques and make a will and squander his property without let or hindrance unless he is made a lunatic by inquisition or unless he is under certificates" (Savage). On the other hand, a medical man who signs a certificate is liable to action on the ground that he negligently and culpably failed duly to inquire into the truth of the facts. A lady named Miss Ethel Hannah Stoeterfoht was placed under the care of Dr. E. N. Reichardt of Ewell and resided in his house. She one day left the house and committed suicide and Dr. Reichardt was indicted on ten counts for "unlawfully receiving and detaining for payment at his residence, Dorset House, Ewell, a lunatic—viz., Ethel Hannah Stoeterfoht—and other lunatics, the said house not having been licensed for the reception of lunatics." The whole trial naturally turned on the question as to whether the patient was or was not a lunatic. The medical evidence was entirely to the effect that the lady was not a person who could have been certified as insane under the Lunacy Act, 1890. The prosecution did not call any medical man to say that she was, and as in such cases medical evidence—especially expert evidence—is rightly considered the means by which such a question should be decided a verdict of "Not guilty" was returned. Dr. Reichardt had done everything he could in the way of treatment for his patient, and although it was afterwards manifested that deliberate preparations for suicide had been made, yet in her general conduct there had been no indications that she was likely to make any attempt upon her life. Great sympathy has been felt for Dr. Reichardt in the position in which he was placed and the verdict has completely exonerated him from any suspicion of professional negligence.

"DOCTOR THERNE."

AT a meeting of the Executive Committee of the Jenner Society held in Gloucester on Dec. 22nd, 1898, the following resolution was passed unanimously:—

"The members of the Executive Committee of the Jenner Society desire to express their appreciation of the recognition of the work of the society by Mr. Rider Haggard in the dedication to its members of his powerful story, 'Doctor Therne.' They also desire to assure Mr. Rider Haggard of their warm sympathy with his just and vigorous protest against the dangerous agitation carried on against vaccination by which many thousands of persons have been misled and have been induced to deprive their children of the only certain protection against a virulent and fatal disease. The committee congratulate Mr. Haggard upon his uncompromising exposure of this evil and trust his book may have a large circulation, as being calculated to lead a considerable section of the public, who cannot be otherwise interested in the subject, to give serious consideration to a matter of urgent and overwhelming importance, affecting, as it does, the health and lives of multitudes of hapless children who may be exposed to the infection of small-pox without the protection afforded by vaccination."

Readers of THE LANCET will remember the high terms of praise in which we were able to refer to Mr. Haggard's romance for its literary vigour and conception as much as for its doctrines.

A CASE OF CHRONIC ONE-SIDED PULMONARY ATELECTASIS.

ON Jan. 4th Mr. E. N. Wood held an inquest upon the body of Charles Lee, aged forty-two years, who had died suddenly on Jan. 1st. Mr. John Mulqueen who was called to see deceased said that upon his arrival he found the patient dead. The cause of death was hæmorrhage. Only one lung had developed. Mr. Mulqueen has kindly sent us the following account of what he found at the post-mortem examination. He says:—

"I made a post-mortem examination on Jan. 3rd and could only find one lung—the right—which was of enormous size extending across the front of the heart and dipping down and fairly well filling the left thoracic cavity. On dissecting the pleura off the back of the left thoracic cavity I came on a small, hard, dark mass which I took to be a rudimentary left lung. At the bifurcation of the trachea the left bronchus was completely obliterated, no air in my opinion ever having entered. There was a cavity at the apex of the right lung of about the size of an egg. The immediate cause of death was hæmoptysis from rupture of a large blood-vessel at the apex."

We fancy that this condition is exceedingly rare. Two cases of congenital absence of one lung were reported by Dr. Wenzel Gruber in Virchow's *Archiv* and referred to in the *British Medical Journal* of Dec. 12th, 1885. Both cases, however, occurred in infants, one of whom was stillborn. The other child had an accessory liver and three accessory spleens. An almost exactly parallel case to that reported by Mr. Mulqueen was commented on in THE LANCET of June 6th, 1885, and communicated by [illegible] Glover to the Islington

Medical Society. Here the patient was sixty-three years of age, the absent lung was the right, and was reduced to a substance resembling a sausage. The left lung was correspondingly large, and the heart was displaced to the right side.

SALINE SOLUTION IN THE HÆMORRHAGE OF TYPHOID FEVER.

THE value of saline injections in hæmorrhage and collapse from other causes is now well attested, though they are not, perhaps, as widely used as they ought to be. Not many cases of their use in hæmorrhage occurring in typhoid fever have been published. In the *Intercolonial Medical Journal of Australasia* Dr. J. Ramsay has published the following case. A man, aged forty-six years, had severe typhoid fever; the temperature was 104·2° F. and the pulse was 100. He passed 8 oz. of blood and on the following day 10 oz. and a few more ounces with the stool. The temperature fell to 97·6°, the pulse was from 70 to 80, the respiration was sighing, and the skin was clammy. Brandy, strychnine, and digitalis were given without effect. The pulse became weaker and unconsciousness and lividity of the hands and ears supervened. He was practically moribund. Two pints of normal saline solution at 100° were injected into the median cephalic vein. Towards the end of the injection the pulse improved in volume and the general appearance became better. But the effect was only temporary. The patient was livid and lay with half-closed eyes, hiccoughing, vomiting, and passing urine involuntarily. Four hours after the first injection one and a half pints of the solution were injected. Improvement again followed, which was more lasting. After this the fever ran the ordinary course, a relapse of ten days' duration occurred, and he slowly convalesced.

OIL OF EUCALYPTUS, B.P. 1898.

THE increased requirements in regard to the quality of oil of eucalyptus as laid down in the British Pharmacopœia, 1898, have led to the prosecution of a druggist in Islington because though the oil he sold complied with the British Pharmacopœia of 1885 it was not in accordance with the characters and tests now officially demanded in the 1898 edition. Accordingly proceedings were taken under the provisions of the Food and Drugs Act which require that the article sold shall be "of the nature, substance, and quality demanded," &c. The evidence showed that the oil purchased was of the character which the British Pharmacopœia, 1898, evidently intended to exclude. The specific gravity was much lower than 0·910, the official minimum limit, its rotatory power was remote from the standard, it yielded no crystals with phosphoric acid which shows the presence of a due proportion of cineol, while the nitrous acid test showed the presence of phellandrene which is said to give rise to an irritating effect when inhaled. The promptitude and activity of the Islington Vestry in starting so soon a plan of campaign under the fresh requirements of the British Pharmacopœia are conspicuous. A conviction was obtained but we cannot help thinking that the action was a little premature and somewhat hard on the pharmacist. The authorities need not have gone so far as to have actually prosecuted for the sale of a drug which last year was in compliance with the British Pharmacopœia but which is not so now. Surely a warning to the druggist would have had the desired, as well as a salutary, effect and have given him a hint to get rid of his old stock and to replace it with new.

SIR RICHARD DOUGLAS POWELL, M.D., F.R.C.P. Lond., has been appointed Physician-in-Ordinary to the Queen in the room of the late Sir William Jenner; Mr. James Edward Pollock, M.D. King's Coll. Aberd., F.R.C.P. Lond., has been appointed Physician-Extraordinary to the Queen in the room of the late Sir Richard Quain; and Mr. Thomas Barlow, M.D., F.R.C.P. Lond., Physician-in-Ordinary to Her Majesty's Household, has been appointed Physician-Extraordinary in the place of Sir R. Douglas Powell.

MESSRS. LONGMANS, GREEN, AND CO. will shortly reissue in a cheaper form Mr. S. Squire Sprigge's work, "The Life and Times of Thomas Wakley."

DR. J. A. SEWELL, one of the oldest British residents in Mentone, died at Beau Rivage last week.

VACCINATION OFFICERS AND THE NEW ACT.

A MEETING of the members of the Vaccination Officers' Association was held on Jan. 7th at the offices, 4, Bessborough-street, W. Mr. Shattocks (Kensington), the President of the Association, occupied the chair and was supported by a large number of vaccination officers from various metropolitan unions and the home counties. A special committee was appointed to consider what steps should be taken to extend the usefulness of the association, which it is intended to convert into a national organisation. In view of the many letters which were read from country officers expressing approval of the efforts which had been made on behalf of the service the chairman urged the absolute necessity of frequent conference among vaccination officers in consequence of the new and important duties cast upon them by the Act of 1898. In the course of general discussion upon the conscience clause of that Act and the extension of the age-period from three to six months the opinion was expressed by most of the officers that these provisions would be prejudicial to securing satisfactory returns in the future, but the belief was expressed generally that as the Government were responsible for the purity of the lymph the bringing of vaccination to the homes of the people would in time be fully appreciated as soon as the alteration was duly appreciated by the public. Aided by the hearty coöperation of the public vaccinator which was held to be indispensable and much to be desired, the members expressed their determination to discharge their new duties as faithfully and efficiently as possible, while it was also held to be a good augury for the future of the new Act that so many busy men in the beginning of a new *régime* should meet together actuated by the sole desire to do their best for the public interest. Some amusing stories were told concerning the "conscientious objector," one officer relating a case in his district where he had received exemption certificates for a number of children and afterwards had received certificates of their successful vaccination—a circumstance which led him to believe that not a few parents were suffering merely from a temporary aberration of conscience.

CHRISTMAS-TIDE AND THE HOSPITALS.

OPINIONS differ as to the wisdom of giving entertainments at institutions specially devoted to the care of the sick, but it is gratifying to see that special care is taken by many of the hospitals to prevent any great inconvenience to those patients whose condition is such that anything but absolute quietness is irritating, if not actually harmful. At St. Mary's Hospital, for instance, special rules were enforced in order "that no one very ill shall be tortured by the noisy enjoyment of those well enough to engage in it." Nevertheless Christmas time is essentially one of "brotherly love" and also one when all Christian peoples endeavour to make their neighbours happy. Especially is this so with regard to the poor and suffering and as long as Father Christmas is venerated efforts of some kind will always be made t cheer the lives of those who through sickness are separated from their friends' during the celebration of this festival We append below brief notes which we have received from the various hospitals

On account of the death of Baron Ferdinand de Rothschild, the founder, there were no festivities at Evelina Hospital.

East London Hospital for Children and Dispensary for Women —The entertainment here provided took the form of a Punch and Judy show, Christmas tree, &c , in addition to which there was a band comprised of several members of the Royal Horse Guards

Royal Free Hospital —The Christmas festivities began on Dec 15th with the students entertainment, which consisted of the well known one-act operetta, *Our Joys*, and *Mrs Jarley's Modern Waxworks*, and some comic songs This was given in two wards and again the following evening in two more On the 19th and 20th carols were sung in all the wards to the accompaniment of stringed instruments and by the light of Chinese lanterns These were followed by the distribution of the usual Christmas gifts of clothing, sweets, and toys Christmas day was celebrated on Boxing day by the sisters' teas to old patients and friends in the wards, which were very prettily decorated On the following day the entertainment of the resident medical officers took place in four wards Mr Williams gave a magic lantern exhibition, Mr. Wyndham Jones ("Captain Spider), an old patient and the "Fly" sang comic songs to the banjo and fiddle, Mr Crispin showed a phonograph, a conjuror performed in two wards, and Mr Tunnicliff sang comic songs On Dec 28th and 29th concerts were given by the sisters in the Milne and Rhodes wards followed by refreshments to the patients and their friends

German Hospital, Dalston —The Christmas festivities took place on Saturday evening, Dec 24th, and consisted of carol singing in the wards, a distribution of useful presents to the patients, besides toys and picture books to the children

St George's Hospital —On Christmas day all the patients who were able to partake of them had roast beef, plum-pudding, &c On Dec 28th a Christmas tea was provided in every ward for the patients when each patient received a gift On Jan 5th the usual entertainment for the patients was held in the board room, when Devant's animated photographs were exhibited, with music, &c On Jan 9th and 10th the annual entertainments for the nursing staff took place, when a programme of music, recitations, &c , was arranged

Royal Hospital for Children and Women —Santa Claus paid his annual visit to the wards on Christmas Eve and the children found his gifts when they awoke on Christmas morning Turkeys and the usual Christmas fare were partaken of by all fit to do so, and for the others suitable good things were provided On Dec 27th there was a Christmas tree, Punch and Judy, and other juvenile delights, and each patient invited one or two guests

St Mary's Hospital —On Christmas day turkeys were provided for dinner and in the afternoon and evening the nurses, medical officers and other friends entertained the patients A case of toys was sent by request of H R H the Duchess of York from Kew children and other friends A large case of toys was received from *Home Chat* Christmas tree and a large parcel of toys, crackers, &c , was received from *Truth* Two cases of Persian dates were received from Mr J B Gray, toys and dolls were received from Mrs Ellis, toys from Mrs Enoch warm underclothing from Lady Surtees, 6 large turkeys from Mr John Aird, M P a box of clothing from Miss Henderson 10 pheasants from Viscount Portman, toys from Miss Dundas Graham, books cards &c , from the Religious Tract Society socks and stockings from Miss Eleanor Barton toys and books from *Little Folks*, and warm clothing from the Hon Miss M Mostyn Each patient in the hospital received a present of clothing and a Christmas letter on Christmas morning, and every man, health permitting received also 1 oz of tobacco and a pipe and was allowed to smoke in the hospital On Dec 28th a Christmas tree for the children was held in the board room Before the distribution of toys there was a Punch and Judy show and after it an entertainment consisting of thought-reading and ventriloquism.

London Hospital —Early on Christmas morning a number of sisters, nurses, and probationers assembled in the nursing home and then walked round all the wards in the hospital singing carols, a proceeding which the nurses enjoyed and which pleased the patients very much Later in the morning Father Christmas and his attendants visited each ward and distributed a present to every patient, each sister having the interesting little packets in readiness for Father Christmas Christmas cards and letters were distributed by the night sisters early in the morning and the wards presented a bright appearance with each patient's new possessions spread out with pride and satisfaction on the bed Christmas fare in the shape of roast beef and plum pudding was provided by the hospital for all those well enough to partake of it Some fortunate wards had gifts of turkeys sent to them In many cases great delight was given to the patients by the fact that their own medical attendant helped to serve the pudding on this festive occasion Later in the afternoon the Christmas tea took place in each ward These teas were followed by a series of well organised entertainments got up by the medical officers and students who worked indefatigably on Christmas day to give the patients a happy time Christy minstrels, Pierrots, farces, comic songs in character, well adapted to the taste of the audience, were given in every ward, the programme being carefully worked out so that the enjoyment never flagged until the cheerful evening was brought to a close at 8 P M Many friends of the medical officers and nurses also visited the hospital and gave songs and recitations Smoking was allowed in the men's wards during the whole of Christmas day and the men looked forward to this privilege with great satisfaction from the time they realised that they were destined to spend their Christmas day in the hospital The tobacco for this festive occasion was kindly provided by the medical officers

Middlesex Hospital —By the energy of the lady superintendent and her friends the patients, nurses, and servants were again each presented with a gift on Christmas morning The serious nature of the illness of most of the patients prevented any dramatic function or concert being held in the wards, but in order to make Christmas as cheerful as possible each of the wards was tastefully decorated and a special Christmas dinner, consisting of turkeys or geese and the usual Christmas pudding, was provided for those well enough to partake of it In the afternoon the patients were allowed to see their visitors and had a special tea provided There was a Christmas tree in the board room loaded with many beautiful gifts, from which each of the patients had something A special feature, however, was the two Christmas trees in the children's wards These trees were unloaded on New Year's day when the children had a tea party It should be remembered that although there were no actual entertainments at the hospital proper the hospital has a convalescent home of its own at Clacton on Sea It is here that the patients as soon as they are well enough are sent and in this home the Christmas entertainment is of a more elaborate character—in fact, the patients there in the winter have one long holiday There is a stage in the dining hall in which sometimes as often as twice a week a dramatic performance is given or a concert is held

North Eastern Hospital for Children —The little patients who had been thinking for many days of nothing but Christmas and the delights which they had learnt from tradition were always associated with that time at a children's hospital found that the fun and enjoyment of the festivities which were celebrated on Bank Holiday far exceeded their highest conceptions Carol singing commenced the day and was followed by the distribution of toys, cards, and sweets of which, through the kindness of many friends of the hospital, there were enough for every child The Christmas dinner was served at midday and the afternoon and evening were spent in the enjoyment of Punch and Judy, a magic lantern entertainment, and in all kinds of Christmas games The festivities were continued on Tuesday with little diminution The committee provided the dinner and the nursing staff and resident medical officers were responsible for the tasteful decorations Christmas trees were provided, decorated, and hung with toys, &c in time for the annual Christmas tree party which took place on Jan 11th Sunday is the usual visiting day and each mother who visited her child on Christmas Day received a present of two articles of clothing for the little ones at home.

Royal Orthopædic Hospital —Christmas day falling this year on Sunday the usual treat to the patients was given on Boxing day. All the wards were tastefully

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING DECEMBER, 1898.

(Specially compiled for THE LANCET.)

SANITARY AREAS.	Estimated population in the middle of 1898.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.†	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

* Including 21 cases of membranous croup.

† Including deaths from membranous croup.

many as 201 below the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Shoreditch, Bethnal Green, Whitechapel, Limehouse, Mile End Old Town, and St. George Southwark sanitary areas The 42 deaths referred to scarlet fever were about half the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Hammersmith and Lambeth. The 174 fatal cases of diphtheria were 32 below the corrected average number; this disease showed the highest proportional fatality in St. Pancras, Limehouse, Mile End Old Town, St. Saviour Southwark, St. George Southwark, Newington, Bermondsey, and Battersea sanitary areas. The 101 deaths from whooping-cough were 80 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in St. Saviour Southwark, St. George Southwark, Newington, and Rotherhithe. The fatal case of typhus fever belonged to Islington sanitary area. The 79 deaths referred to enteric fever were 14 above the corrected average number; this disease showed the highest proportional fatality in Fulham, Marylebone, Hampstead, St. George Southwark, and Lewisham sanitary areas. The 65 fatal cases of diarrhœa slightly exceeded the average. In conclusion, it may be stated that the aggregate mortality in London last month from these principal zymotic diseases was more than 36 per cent. below the average.

Infant mortality in London during December, measured by the proportion of deaths of children under one year of age to registered births, was equal to 122 per 1000, and was considerably below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, Westminster, Stoke Newington, St Olave Southwark, Lewisham, and Greenwich; and the highest rates in Chelsea, Holborn, Poplar, St. George Southwark, Newington, Bermondsey, and Lee.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

FLEET SURGEON VALENTINE DUKE is placed on the retired list with the rank of Deputy Inspector-General of Hospitals and Fleets.

The following appointments are notified:—Fleet Surgeons: A. W. Russell to the *Pembroke*, for Chatham Dockyard; J. L Sweetnam to the *Pembroke*, temporary; A McKinlay to the *Howe*; and A. H Miller to the *Resolution* Staff Surgeons: J. C. F. Whicher to the *Melampus*; F. J. Burns to the *Pactolus*; W. Eames to the *Theseus*; W S. Lightfoot to Plymouth Hospital; J. Barry to the *Pegasus*; G H. Foott to the *Pelorus*; and H. W. Macnamara to the *Boscawen*. Surgeon J. Martin to the *Theseus*.

ARMY MEDICAL SERVICE.

Surgeon-General W. Taylor, to be Deputy Director-General. Lieutenant Colonel W. L Gubbins, Royal Army Medical Corps, to be Assistant Director. The under-mentioned officers of the Royal Army Medical Corps to be Deputy Assistant Directors:—Major W G. A Bedford and Major W. G Macpherson.

ROYAL ARMY MEDICAL CORPS.

Major E H Myles is posted to the Punjaub, Major G F. Gubbin to Bengal, and Majors R H Forman and F. J. W. Stoney to Madras. Captain Rawnsley embarks for Bombay, Captain R J. Copeland joins at Woolwich, and Lieutenant G S Nickerson embarks for Egypt Major H G. Hathaway is directed to join at Woolwich

Captain Alexander J Chambers is placed on temporary half-pay on account of ill-health

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain M. Mackenzie to be Surgeon-Major; Surgeon-Captain Robert Mitchell, 1st Volunteer Battalion the Lancashire Fusiliers, to be Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 4th Durham (Western Division, Royal Artillery): Surgeon-Lieutenant-Colonel S. Gourley resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. *Rifle*: 1st Volunteer Battalion the Buffs (East Kent) Regiment: Arthur Ernest Larking to be Surgeon-Lieutenant. 1st Herefordshire: James McKean to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment): Second Lieutenant A. D. Howard to be Lieutenant; Surgeon-Captain H. G. G. Wilkins resigns his commission.

THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The following officers who have been under instruction from the staff of the school have recently passed the proficiency examination conducted by the officers of the Royal Army Medical Corps at the headquarters of regimental districts—viz.: Surgeon-Major C. Godson, Army Medical Reserve of Officers; Surgeon Captain A. Abraham, 5th Volunteer Battalion Durham Light Infantry; Surgeon-Lieutenant J. W. Edwards, Tees Volunteer Division Submarine Miners, Royal Engineers; Surgeon-Lieutenant J. F. Fotheringham, Queen's Own Rifles of Canada; Surgeon-Lieutenant D. G. Newton, 1st Volunteer Battalion York and Lancaster Regiment; Surgeon-Lieutenant J. F. Hall, 3rd Volunteer Battalion "The Queen's" Royal West Surrey Regiment; Surgeon Lieutenant J. F. McCann, 1st Middlesex (Victoria and St. George's) Rifle Volunteers; Surgeon-Lieutenant J. E. Bates, Bearer Company, Surrey Volunteer Brigade; Surgeon-Lieutenant J. Allison, 1st Volunteer Battalion Northampton Regiment; Surgeon-Lieutenant J. W. Bone, 3rd Volunteer Battalion Bedfordshire Regiment; Surgeon-Lieutenant D. Monro, 1st Galloway Rifle Volunteers; Surgeon Lieutenant W. K. Paull, 3rd Volunteer Battalion Bedfordshire Regiment; Surgeon-Lieutenant J. Oldfield, 1st Volunteer Battalion Essex Regiment; Surgeon-Lieutenant C. Stephens, 3rd Volunteer Battalion Suffolk Regiment; Surgeon-Lieutenant J. Forsyth, 1st Essex Volunteer Artillery; Surgeon-Lieutenant W. T. Crawford, 4th Volunteer Battalion Derbyshire Regiment; Surgeon-Lieutenant P. D. Minchin, 2nd Volunteer Battalion "the Queen's" Royal West Surrey Regiment; Surgeon-Lieutenant J. Raywood, 5th Volunteer Battalion the South Wales Borderers; Surgeon-Lieutenant L Demetriadi, 2nd Volunteer Battalion (the Duke of Wellington's) West Riding Regiment; Surgeon-Lieutenant J. W. Cook, 1st Volunteer Battalion the Lancashire Fusiliers; Surgeon-Lieutenant C. Bucknill, 2nd Volunteer Battalion the East Lancashire Regiment; Surgeon-Lieutenant D. Hamilton, 4th Volunteer Battalion the Manchester Regiment; Surgeon-Lieutenant E. McCarthy, 4th Volunteer Battalion the Cheshire Regiment; Surgeon-Lieutenant G. Hawkins-Ambler, 1st Lancashire Royal Engineers Volunteers; Surgeon-Lieutenant A. Renshaw, 3rd Volunteer Battalion the Cheshire Regiment; Surgeon-Lieutenant C T. Green, 1st Volunteer Battalion the Cheshire Regiment.

THE MEDICO SANITARY ASPECT OF THE SPANISH-AMERICAN WAR

Mr Carroll Dunham, writing in the *Revue Scientifique* of Jan. 7th on the medical and sanitary aspect of the Spanish-American War, repeats the often-told story of the inadequacy of the supplies forwarded to the American army in Cuba and of the failure of the transport authorities to convey the medical stores. The medical service of the Army Corps attacking Santiago had at their disposal the campaigning hospital of the first division, erected three miles east of Santiago, a hospital on the shore, and the hospital ship *Olivette* at anchor in the bay. On July 1st the hospital of the First Division consisted of three large tents for the operation tables and the pharmacy; a fourth large tent was reserved for wounded officers and half a dozen smaller tents for soldiers There were 5 surgeons with less than 20 ward attendants. The hospital was capable of receiving 100 wounded, but it had no hammock, mattress, or pillow, the number of blankets was very small, and for spare linen there were only three dozen shirts. There was no food whatever for the patients except a little extract of meat and condensed milk brought in the luggage of one of the surgeons As for the means of transport, there were only three ambulances in the whole army. The wounded commenced to arrive at 9 A M on July 1st They lay on the grass exposed to the tropical sun by day and at night they took cold. The surgeons were on their feet twenty one hours without rest, working all day, and at night by candle light, fired at by Spanish riflemen perched in the trees. Malaria was inevitable and yellow fever was introduced by refugees from the town. Things were not much better on the way back to America: The first ship, the *Seneca*, arrived at New York with about 100 sick and wounded.

The condensers could not provide enough fresh water so the wounds were washed with sea water and the passengers had to tear up their shirts to make dressings. The *Concho*, provided with 58 beds, arrived on July 29th with 172 sick and wounded. She had on board one medical officer who was himself suffering from illness and with him there was one hospital attendant.

THE ROYAL ARMY MEDICAL CORPS.

The *Army and Navy Gazette* of Jan. 7th, in dealing with the history of the military year, 1898, makes the following remarks: "The Army doctors have had their hearts gladdened, after years of vigorous agitation, by the issue of a Royal Warrant according to them the right of bearing military titles, whilst the old Medical Department, lately the Medical Staff, is now constituted a Royal Army Medical Corps. What the effect will be in attracting young men to the service remains to be seen, but at any rate some of the most pressing wants of the gallant and devoted body of men who are charged with the care of the sick and wounded have been met and Lord Lansdowne has thus earned the gratitude of the profession at large. It is for the profession of medicine now, the heads of schools before all, to show a proper appreciation of favours and assist the War Office to secure candidates in every sense suitable. If this is done we have no doubt the military authorities will even go farther than they have at present in their endeavours to make the position of the Army medical officer comfortable and attractive. The future of the Army doctor now depends largely on the Army doctor himself and those who have influence over him outside the service. All the War Office for the moment can do is to watch events and be guided by the action of those to whom it looks for support. The support of which we speak ought certainly to be forthcoming."

THE SOUDAN EXPEDITION.

Since the occurrence of the battles at Atbara and Omdurman the remaining portion of the Dervish force under Ahmed Fedil has been attacked whilst crossing the Nile and badly defeated by Colonel Lewis, in command of the 10th Soudanese and some irregulars. We infer from Lord Cromer's speech to the Soudanese chiefs and sheikhs regarding the future policy of the Egyptian and British Governments that the conquered country is to be divided into districts and temporarily administered under resident military officials, very much as is done in India. We are naturally glad of this because it is what we have already indicated as in our opinion the best course. A few years' peace under such administration and government, will bestow a degree of prosperity, health, and happiness on the dwellers in the Soudan which they have not known for many years past—if they have indeed ever done so before.

THE ARMY MEDICAL SERVICE.

The announcement in the *London Gazette* of Jan. 10th of the new titles conferred upon medical officers serving at the Headquarter Office of the Army Medical Service was no doubt a cause of more or less surprise. Our interpretation of its object is, however, that it is simply with a view of placing the medical service upon a similar footing to that of other branches of the military service by assimilating the titles of medical officers in the Director-General's office to those of other military officers holding staff appointments in the War Office. The announcement in question, given on the previous page, is:—

Army Medical Service.—Surgeon-General W. Taylor, M.D., C.B., to be Deputy Director-General. Lieutenant-Colonel W. L. Gubbins, M.B., the Royal Army Medical Corps, to be Assistant-Director. Majors W. G. A. Bedford, M.B., and W. G. Macpherson, M.B., of the Royal Army Medical Corps, to be Deputy Assistant-Directors.

LEAN'S ROYAL NAVY LIST.

The eighty-fifth quarterly issue of this practically indispensable handbook is now on sale at the publishers, Messrs. Witherby and Co., 326, High Holborn, and 4, Newman's-court, Cornhill. Constant reference to its pages confirms its accuracy and the publication is now so well known as to make description unnecessary. The present issue is brought up to date and the work forms, as it has always done, a complete storehouse of reference with regard to our first line of defence.

THE APPOINTMENT OF MEDICAL OFFICER ON THE NEW VICEROY'S STAFF.

Lieutenant-Colonel H. Fenn, of the Royal Army Medical Corps, went from Calcutta to Bombay on the arrival of Lord Curzon in order to take up his appointment as Medical Officer of the Viceroy and his Staff.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on Jan. 10th, Inspector-General W. H. Lloyd, M.D. St. And., in the chair, the sum of £65 was distributed among the several applicants.

THE AMEER OF AFGHANISTAN.

The Ameer, according to recent intelligence from Cabul, is stated to be seriously indisposed. In the event of his death political complications and difficulties may very probably arise in Afghanistan.

DEATHS IN THE SERVICES.

General Sir James Mouat, V.C., K.C.B., on Jan. 4th, at his residence in Palace-gardens-terrace, Kensington. (An obituary notice will be found in another column of THE LANCET.)

Lieutenant-Colonel R. Macrae, Indian Medical Service, Civil Surgeon of Dacca, has been appointed Civil Surgeon of the First Class, vice Lieutenant-Colonel R. D. Murray, Indian Medical Service.

Her Royal Highness Princess Christian of Schleswig-Holstein has consented to present the prizes to the London Companies Volunteer Medical Staff Corps, on Friday, Jan. 27th.

Correspondence.

"Audi alteram partem."

VACCINATION LITERATURE.

To the Editors of THE LANCET.

SIRS,—It has been suggested to me that the members of the medical profession might give valuable help in educating the public in the cause of vaccination by allowing samples of Jennerian literature to be on the tables of their waiting-rooms where they might be seen by their patients and others. The Jenner Society will be happy to supply such literature to anyone who will apply for it. I am glad to find from communications I am increasingly receiving that the members of the profession are beginning to take a much more active part than they have hitherto done in this good work by giving lectures and addresses on the subject, by correspondence in the public papers, and by joining in debates on it. I shall be pleased to give any assistance in this direction to any who may desire it.

I am, Sirs, yours faithfully,
FRANCIS T. BOND, M.D. Lond.,
Gloucester, Jan. 3rd, 1899. Honorary Secretary Jenner Society.

"RECRUDESCENCE OF PSITTACOSIS."

To the Editors of THE LANCET.

SIRS,—I see that your correspondent at Rome sends you an account[1] of the recrudescence of this complaint in Italy. It is endemic in this country and if cases are not notified it is that they are not recognised. Something over a year ago you were good enough to publish my views upon the subject, which views I have since seen no reason to modify. Still there is a danger that the disease may spread to human beings by contact with the diseased parrots and especially so if people are uncleanly enough to put the birds' bills into their mouths. One firm of importers states in its advertisements that it receives 80,000 (eighty thousand) grey parrots a year, and I have the best of reasons for saying that these birds invariably die within six weeks of their arrival from psittacosis, a form of fever akin to typhus, and they will continue to do so until either the public ceases to buy or the supply of parrots fails.

I have called attention to this excessive mortality for years past but it still goes on and there is no doubt that there is a risk of the fever extending its sphere of destructiveness. At first it was confined to the grey parrot, but now I find evidence of its fatal effects in other birds of the same family but different species coming from West Africa, and also, quite lately, in other birds, and although inoculation failed to convey the disease to pigeons and guinea-pigs, exposing the former to immediate contact for some days with a death-smitten parrot was effective in transplanting the fever. So it may go on, and probably will, unless something is done to purify the dens to which the birds are conveyed on their arrival at the coast, the cages or crates in which successive batches are imported, and even the part of the ship in which the poor creatures are lodged during the voyage.

---

[1] THE LANCET, Dec. 10th, 1898, p. 1591.

To show how deadly is the scourge and how persistent the infection people have written to me to say that they have had several (from 3 or 4 to 20) die within a few weeks of buying them, and they could not imagine why it should be so, for not only had they taken every precaution in the ordinary way but they had lost birds which had been brought over privately and which had never been near a dealer's shop. The explanation is simple. The cage in which one of these birds has died is henceforth a source of infection and can only be cleansed by stoving, all domestic methods of disinfection utterly failing to stamp out the germs of the disease which I have reason to believe has its origin in overcrowding and dirt.

Personally I have failed to trace any connexion between fever in a favourite parrot and any ailment subsequently manifested by its master or mistress, but I can conceive that such is possible; therefore it is high time that sanitary authorities should interfere and see that the "emporia" whence these birds are distributed over the country are put into a healthy, wholesome condition, or if this be found impossible that they be compulsorily closed, for humanity revolts at the thought of the wholly preventable massacre of the innocents and its possible consequences. All dealers in livestock should be compelled to take out a stiff yearly licence and their premises should be periodically inspected by competent officials who should report to a central authority vested with sufficient power to put down a nuisance of which the consequences may soon prove to be more dangerous to the public welfare than is generally supposed.

I need say no more about bird and pet stores; anyone who likes can make a tour of those in London and judge for himself or herself, but I have no hesitation in affirming that the result will be a prompt decision that something should be done, and done quickly. I find that although the lungs are affected in some cases the disease concentrates its virulence in the liver, kidneys, and more particularly the spleen.—I am, Sirs, yours faithfully,

W. T. GREENE, M.D., T.C.D., F.Z.S., &c.

Belvedere, Kent, Jan. 4th, 1899.

POISONING BY BROMOFORM.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 31st, 1893, your Manchester correspondent records a case of poisoning by bromoform in Lancaster. I think the following case may be of interest as it seems to resemble the one mentioned with the great difference that my patient recovered.

In the early part of last year my partner's five children were suffering from pertussis and, other remedies failing, he decided to try bromoform, one and a half drachms of which were put in a mixture made up to eight ounces with mucilage and water. The eldest girl, aged eight years, took one tablespoonful and the others smaller doses according to their ages; for four or five days they took the medicine and were so benefited by it that it was discontinued. On the sixth day, about 4 30 P.M., I was sent for, as my partner was out, and on arriving I found the eldest girl in the following critical condition. She was lying in a wholly unconscious state, snoring deeply. Both pupils were strongly contracted and hardly reacted to light. The conjunctival reflexes were almost lost, the pulse at the wrist was scarcely perceptible, and the heart-sounds were very weak. The face was pinched and the lips were blue. I gave two drachms of ipecacuanha wine which produced fairly free vomiting, and followed this up by a hypodermic injection of $\frac{1}{16}$ gr. strychnine and applied hot flannels over the heart. As the improvement in the child's condition was very slight I gave an injection of two drachms of whisky under the skin of the chest and an enema of strong coffee. The pupils were now more dilated and the pulse was better in strength and quality and though still unconscious the patient's general condition had improved. Her father then returned and drew my attention to a peculiar sweetish smell which was evolved from the vomit and breath and on inquiry we received the following particulars of the onset from the mother. The girl had a violent fit of coughing at 3 P.M. and was given a dose of the bromoform mixture, the last in the bottle. She then lay down. From half to three-quarters of an hour later her mother heard loud snoring issuing from the room and being unable to rouse the child sent for me. About 8 P.M. the patient recognised her father and seemed to be improving. At 10 P.M. there was a change for the worse; the character of the respiration, however, changed from the loud snoring to a soft sighing, becoming so feeble that we resorted to artificial respiration. Owing to the recurrence of the symptoms we suspected that some of the drug must be left in the stomach which we accordingly washed out with an ordinary syphon pump and noticed that the water which returned had the same sweetish smell, which smell the child's breath retained for several days. The remaining treatment through the night consisted in putting the patient near an open window, where she gradually recovered, and with the exception of a very bad headache the next day she did not seem much the worse for the misadventure.

I am, Sirs, yours faithfully,

HAROLD W. EVANS.

Littleport, Cambs, Jan. 9th, 1899.

"THE 'OPEN-AIR' TREATMENT OF TUBERCULOSIS."

To the Editors of THE LANCET.

SIRS,—Your correspondent, Staff-Surgeon Gipps, in his anxiety to emphasize the value of Alpine climates has been guilty of some exaggeration and aroused the suspicion that he knows little of the results obtained in non-Alpine sanatoria in Europe and America. Anybody who had not specially studied the subject would be led by a perusal of Staff-Surgeon Gipps's letter to believe that the open-air treatment is only possible in Alpine and other specially favoured climates. Alpine sanatoria need no puffing, but they are by no means suitable for every case of consumption, even in an early stage, and are not available for the majority of suitable cases in this country. It is therefore fortunate that exceedingly good results are obtained in non-Alpine sanatoria, which constitute by far the larger number of those in existence, and some of which are no more favoured by soil and climate than many parts of the British Isles.

The results in non-Alpine sanatoria of Germany were sufficiently good to warrant the insurance companies there in paying between three and four million marks in 1898 for the maintenance and erection of such sanatoria for the people. One of these insurance companies has published elaborate statistics of 1541 phthisical patients, showing that in such sanatoria general improvement has taken place in 85·5 per cent., local improvement in 61·1 per cent., and complete restoration of working capacity in 71·8 per cent. In 15·5 per cent. the local signs were slight on admission and disappeared during treatment; in 15·4 per cent. they were unchanged; in 42·6 per cent. the local signs were well marked on admission and greatly improved on leaving; in 13·9 per cent. the local signs remained of a well-marked character and in only 6·6 per cent. they increased. It is also shown that a large proportion of those treated in former years have remained well. This is but one out of many examples of the value of rational treatment in medically-managed sanatoria even where the climate is not ideal. For the sake of the many who cannot go abroad, owing to expense, domestic ties, and a variety of medical and other reasons, I would urge Staff-Surgeon Gipps to be less sweeping and more accurate in his statements and not try to take from such patients their best hope of recovery. To exalt the value of climate (great as it is) at the expense of medical supervision of the details of daily life is a most dangerous policy which will only lead to a further extension of the "go-as-you-please" methods which are answerable for at least half the failures. What has been done in the Sharon Sanatorium in a consumption-ridden district, and at German hill sanatoria where the weather and climate are at times far from ideal, can certainly be approached, possibly equalled or surpassed, in our own land, while many lives will thus be saved which under less careful and systematic treatment would inevitably drift to an unfortunate end.

I am, Sirs, yours faithfully,

Welbeck-street, Jan. 3rd, 1899. F. RUFENACHT WALTERS.

A QUESTION IN ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—I think anyone reading the able article in THE LANCET of Dec. 17th entitled "On the Administration of a Certain Mixture of Chloroform and Ether in Gynæcological Operations by Means of a Clover's Inhaler without the Bag" must be struck with one idea—namely, if the long ago admitted advantage of a combination of ether and chloroform is so safely and easily given in a "Clover," how is it that the London anæsthetists do not use it for this purpose and why are some of them experimenting with an elaborated instrument such as has been described in the Transactions of the London Society of Anæsthetists? We are usually taught to carefully avoid giving $CHCl_3$ in a closed apparatus of any kind. Have we to reconsider this point? I think most medical men have satisfied themselves that chloroform is a dangerous anæsthetic and to give ether without gas is almost cruelty, for all patients describe the first half minute of the administration as truly awful, and then the after nausea and pain in the throat are most disagreeable. I think the London anæsthetists owe to the profession a definite criticism of the above-mentioned paper for or against it.

I am, Sirs, yours faithfully,

St. Day, Cornwall, December, 1898. E. H. WORTH.

OPIUM-SMOKING.

To the Editors of THE LANCET.

SIRS,—I implicitly recognise the superior wisdom of your reviewer who in THE LANCET of Dec. 31st, 1898, meets every statement in a recent book of mine somewhat in the manner of Mr. Burke's celebrated colleague—by a flat contradiction. Still, he makes one assertion so opposed to the experience of all who have any practical acquaintance with the subject that I think he should condescend to furnish some corroboration. I remarked that opium cannot possibly be smoked like tobacco, every particle of alkaloid being thus promptly burnt up and not volatilised. That, he says, "is contrary to the experience of many." Will he kindly give his authority *or cite a single instance in* which a person has felt the slightest opium influence by smoking opium in any other way than with the one form of pipe perfected by generations of Chinese? He may have been misled by the popular fallacy that Manilla cigars are soaked in laudanum, but has no right to publish that as scientific fact.

The inhalation of the volatile opium alkaloids under medical supervision is a therapeutic power of high value hitherto unduly neglected. Without *recapitulating* all the maladies in which it is of use it may suffice to say that pain of every kind is relieved by the anodyne effects, chronic wasting disease of all species by the capacity to check tissue-waste. The latter point indicates its employment in advanced age to promote longevity. Hence if your reviewer can indicate some easier method than the rather delicate technique of the ordinary opium apparatus of procuring these benefits he will confer a boon on many such sufferers.

I am, Sirs, yours faithfully,

HERBERT SNOW.

Gloucester-place, Portman-square, W., Jan. 3rd, 1899.

⁂ In expressing our dissent from Dr. Snow's statement that if opium be smoked like tobacco all the essential principles are burnt up and none inhaled we based our opinion chiefly on our personal knowledge of cases in which the usual anodyne and hypnotic effects of the drug have followed its administration in this manner. The superiority of the Chinese method of smoking opium consists in the fact that when it is employed a much larger proportion of the active principles is inhaled than when the drug is smoked with tobacco in an ordinary pipe.—ED. L.

MILITARY SERVICE FOR MEDICAL MEN IN FRANCE.

To the Editors of THE LANCET.

SIRS,—May I correct a mistake that was made in THE LANCET a few months ago? The period of military service is not three years for University students. The medical student is obliged only to serve for one year; the two remaining years are due only if he is not *docteur ou interne* at the age of twenty-seven years, which happens very seldom indeed.

I am, Sirs, yours faithfully,

HENRY COINTEPAS,
Externe des hôpitaux de Paris.

Rue Franklin, St. Denis-sur-Seine, France, Jan. 5th, 1899.

THE CONSCIENTIOUS OBJECTOR.

To the Editors of THE LANCET.

SIRS,—Since the appointment of the Royal Commission, although there is at present a lull in the storm, the cost to the country from small-pox has been enormous, to say nothing of the dreadful suffering and deaths (known only to those who witness them), and now vaccination costs more than double and is rendered inefficient. No wonder, therefore, that boards of guardians are flatly refusing to carry out the Act. Will our non-conscientious legislators take any steps towards remedying the error they have committed? It appears to me the least they can do, and that without a day's delay, is to pass "an Act to amend the Vaccination Act." No doubt when the conscience clause was passed it was thought that the magistrates who had no votes to lose would act as a buffer between the Members of Parliament and the anti-vaccinationists, and nice buffers they are proving themselves.

The Act reads that "they are to *satisfy* themselves that a man has a *conscientious* objection," and how are they doing it? In one instance a long row of applicants were told to *hold up their hands*, and all who did so were granted certificates. Now if the Act had been worded in such a way that certificates were to be granted to "those who had a simple objection" or "to all applicants" the magistrates would not be guilty of dereliction of duty, as they now are. With a few notable exceptions—such as Mr. Corser and Mr. Mead—they are incurring an awful responsibility by this neglect of duty. The Vaccination Act is now literally left to them to carry out and although they ought not to have been put into this position they should either do their duty or resign or, as one medical magistrate has done, retire from the bench when applications are made. Instead of that they often do not even charge the highest fees and make all the difficulty they can, but on the contrary encourage the ignorant and misguided in their wicked folly.

Vaccination is now made perfect by the new Act and instead of giving it a trial which in time would even convince a rabid anti-vaccinationist, it is being rendered nugatory. A day of reckoning will surely come, as unless the evil is at once remedied ages yet unborn will live to curse us when for want of a simple precaution there will be a return to the days of the Black Death with its fearful cordon of isolation as the only means of escape. If the plain and guilty alone suffered it would be different, but there are the comely and innocent who have to be considered when, if life is saved, disfigurement, blindness, deafness, and other sequelæ (very common in the worst form of small-pox of which this generation knows nothing) render that life worse than death.

I am, Sirs, yours faithfully,

WILLIAM WOODWARD, M.D. St. And.,
Late Public Vaccinator for upwards of thirty years
to the Worcester District.

Worcester, Jan. 10th, 1899.

"THE PAY OF COLLIERY SURGEONS."

To the Editors of THE LANCET.

SIRS,—I read with great interest your comments on the pay of colliery surgeons in Durham in THE LANCET of Nov. 12th, also on the pay of colliery surgeons in the Eastern Valleys, Monmouthshire, in THE LANCET of Dec. 24th, 1898. In the annotation on Dec. 24th it is mentioned that the Western Valley surgeons were paid better than the Eastern Valley surgeons. I can only compare the pay of the Western Valley practitioners with that of their Durham brethren as I do not know how they are paid in the Eastern

Valleys. Here they are paid by stopping twopence per week per man for every pound he earns. Taking an average for the last few years the pay has been in this part under twopence per man per week, or if we had been paid as the Durham surgeons had been paid—i.e., threepence per man per week—our income would have been considerably larger. This average does not include the six months' strike in which the medical attendance was continued and there was no pay. Twopence in the £ covers all the medical attendance and what drugs they want other than the drugs prescribed—i.e., vaseline, castor oil, &c.

I am, Sirs, yours faithfully,
WESTERN VALLEY SURGEON.

Nantyglo, Mon., Jan. 2nd, 1899.

A PRACTICAL EXAMINATION PAPER.

To the Editors of THE LANCET.

SIRS,—I enclose a copy of the paper set by the Conjoint Board in the Second Examination in Physiology as a specimen of what such a paper ought to be. The six questions give a good range of subjects, all of which ought to be familiar to the student who hopes to be a practitioner. I wish the examiners for the Fellowship would follow suit.

I am, Sirs, yours faithfully,
AN OLD EXAMINER.

[ENCLOSURE.]

1. What are the functions of the roots of the spinal nerves? By what experiments have these been determined?
2. Describe the voluntary muscle fibres. State how you would make a microscopic preparation to show their structure.
3. Describe the muscular mechanism of the respiratory movements. What influence have these movements on the circulation?
4. How can the velocity of the blood stream be determined in an artery, a vein, and a capillary? How and why does the velocity vary in each kind of vessel?
5. Describe the digestive processes that occur in the small intestine. State the parts played by the pancreatic juice, bile, and succus entericus respectively.
6. How would you estimate the urea in urine? How is urea formed in the body?

PRESERVED GLYCERINATED CALF VACCINE.

To the Editors of THE LANCET.

SIRS,—The results of the trials of calf vaccine during the year 1897 which were published in THE LANCET of April 23rd last have been valuable in proving (1) that as a general rule the average length of activity of glycerinated calf vaccine is limited to a few weeks only, during which time the activity varies inversely with the age and therefore that it cannot be relied upon for any given period, and (2) that reliable calf vaccine has been obtained during the colder months and in the heat of the summer and autumn. It also appears (from private records and observations) that certain different characteristics of the calves do not affect the quality of the vaccine taken therefrom, for example, both active and inactive vaccine have been generated upon calves of the same colour, age, weight, and sex when vaccinated with the same care, by the same person, in the same place and with equally reliable vaccine. Nor does the examination of the dead carcass yield any proof of activity of the vaccine taken from that particular animal. It therefore appears certain that with our present knowledge and experience it is impossible to produce *at will* calf vaccine which is active and will retain its activity for any definitive period, though cases appear (as if by accident) where a calf will generate fine vaccine which will retain its activity for a much longer period than is sufficient for all practical purposes. Here it may be questioned whether bacteriological investigations may not be out of place until the good quality of the vaccine has been ascertained, in order that when the bacteriologist has satisfied himself that the "extraneous microbes" have disappeared he may also be certain that the activity of the vaccine has not also disappeared, if it were ever present.

Though we are at this time unable to select with certainty an animal upon which vaccine of prolonged activity may be generated a study of the facts made evident from long experience may give us that desirable power. These facts are, first, that the more reliable vaccine is generally that which is produced in the cold months, and, secondly, that a great factor of unreliability is changeable weather. All that has been said of calf vaccine must be also applicable to human vaccine.

From these considerations the importance of being able to select such calves as will generate vaccine of the quality desired is evident and it naturally follows that to obtain with certainty perfect vaccinations in man or animal we must discover that condition in either which will reproduce in its system similar results for both cases—the patients and the animal must be synonymous. In each case the soil must be studied as well as the seed; both must be suitable for the end desired.

It is quite certain that the inability to judge of the activity of vaccine taken for storage obtains both in the public vaccinator using human vaccine and the producer of calf vaccine, for both are alike ignorant as to the reliability of the vaccine which they have stored. The more perfect mixture of the vaccine and glycerine by the invention of Dr. Chalybäus has perhaps done more to preserve the activity of calf vaccine than anything else.

I am, Sirs, yours faithfully,
A. B. C.

Dec. 19th, 1898.

*** *Our correspondent is referred to an annotation on* p. 107.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Commission at Hyderabad.—The Progress of the Epidemic.—The Report of the Austrian Commission.

THE Plague Commission held their first sitting in *Hyderabad on Dec.* 19th, 1898, when Lieutenant-Colonel Lawrie, I.M.S., Mr. Stevens, Dr. Mullanah, and Captain Johnson, I.M.S., were examined. Lieutenant-Colonel Lawrie first described the measures which had been taken in the Nizam's dominions to stamp out the epidemic. The disease was probably conveyed into this district by refugees from Sholapur. The measures were (1) evacuation of the infected villages, (2) destruction of the infection by burning the floors and walls (surfaces) of infected houses by fire, and (3) disinfection of useless clothing and bedding by burning and of bedding and clothing generally by boiling. Lieutenant-Colonel Lawrie was a strong advocate *for disinfection* by fire for the following reasons: (*a*) it destroyed the infection of the disease; (*b*) it cost the Government nothing except for supervision, the people willingly employed it themselves under (our) trained agents and workers; (*c*) it was popular with the villagers and ryots; and (*d*) it not only destroys infection but it also destroys the food the plague microbe likes and by which it is kept alive and toxic. The people remain in their camps and do not scatter themselves to spread the disease over the country. Lieutenant-Colonel Lawrie stated that rats inoculated with floor scrapings in which the bacillus was found died with all the symptoms of plague and the same bacillus was discovered in their glands and blood. He asserted that the plague bacillus could be separated from the dust of floors in plague-infected houses. He recounted one result of his visit to Bombay where he discovered the plague germ at one hospital in the ground where an old man had lain for several days beside the cot of his sick grandchild and had then contracted plague and died. A rat which was inoculated with a solution made from this floor scraping developed the symptoms of plague and died. The same bacillus was found in its tissues and organs.

With reference to Haffkine's fluid and inoculation for plague Lieutenant-Colonel Lawrie made some extraordinary statements. He said that Haffkine's fluid was not a serum but a putrescent *organic liquid*—a putrid broth containing a large number of the micrococci of putrefaction and occasionally pathogenic organisms. He said he could not conscientiously recommend it and he did not consider it right to perform such an operation as inoculation with a fluid containing putrid organisms. He said that what was practically compulsory inoculation led to the spread of plague by causing people to fly from their homes. He was aware that there were other bacilli which closely resembled the plague bacillus morphologically but he did not know that such bacilli were commonly found in water and in soil. He admitted that large doses did protect rabbits to a considerable extent.

With regard to this evidence it may be said that inoculation has been everywhere absolutely voluntary and it has been stated over and over again in official notices that inoculation is entirely optional. Lieutenant-Colonel Lawrie implies that the fluid used is not sterile and that no proper experiments have been made to ensure this (which is incorrect). According to Lieutenant-Colonel Lawrie the inoculation fluid of M. Haffkine is calculated to produce blood-poisoning, abscesses, and ulceration. As a matter of fact it does not. In Bombay alone over 32,000 persons of all classes and races have been inoculated and not one has been overtaken by the dire results attributed by Lieutenant-Colonel Lawrie to inoculation. It is obvious that had the fluid been found to contain the organisms of putrefaction it would have been prohibited immediately. Moreover, the Director-General who was himself inoculated has reported to Government after extensive inquiry that its results are most encouraging. Dr. Yersin was supposed to have found plague microbes 7 in. below the soil but these Dr. Bitter said were not plague microbes at all. Others have tried to find them and have failed. Every one knows that the Government have not been hasty in judging of the effects of inoculation and were Lieutenant-Colonel Lawrie's statements even partially true the operation must have been condemned long ago. Mr. A. H. Stevens, the Deputy Plague Commissioner, said that the Nizam's Government remained in absolute ignorance of the outbreak of plague in Hyderabad territory until about two months after its actual appearance. The difficulty in plague work is to obtain early information. He said that the villagers fully recognised the value of evacuation which had been carried out in every village infected with plague. The method of disinfection which he had employed with apparently great success was the kiln method of burning the floor surfaces and of burning and boiling the bedding and clothes. The method destroys infection, costs little, and is popular.

The plague returns for the Bombay Presidency show very little improvement, there being 2697 deaths recorded as compared with 2728 the week previously. In Bombay city there were 106 deaths from plague as compared with 75 in the week preceding. Karachi does not seem to be able to absolutely clear itself, a new case now and again appearing, and Poona also reports two fresh attacks and deaths. The Poona district generally shows higher figures. It is reported that at railway stations where medical inspections take place 24 cases only were detected. After a long interval which led to the hope that plague had disappeared from the Punjab 2 more cases have occurred at the town of Rahon in the Jullunder district. At Bangalore on Dec. 18th Professor Wright of Netley, a member of the Plague Commission, inoculated some 250 men and officers of the 2nd West Riding Regiment against enteric fever.

The portion of the report of the Austrian Commission of most interest is that containing the late Dr. Müller's conclusions concerning the pathology of infection. He thought that the disease originated in an infection through the skin which remained localised for a time, but that primary plague pneumonia unquestionably entered through the respiratory passages. He contended that in all cases (except, perhaps, the pneumonic) there was glandular swelling, although the primary bubo might not be discoverable. Dr. Müller did not agree with those who held that in all cases of recovery the bacilli remained localised in the swelling and did not invade the blood. He said that "a patient does not die because he has bacilli in his blood and does not recover on account of their absence." He thought that whether the organism would triumph over the disease depended upon the degree of natural power it possessed against the poison of the plague. He said that general infection (of the bacilli) had occurred in patients who had recovered. (Most authorities hold that the presence of bacilli in the blood is a certain sign of a fatal termination.) Those who hold Dr. Müller's views—viz., that it matters little whether the bacilli invade the body or not—are opposed to interference with the gland, to experimental punctures, to large incisions, and to clearing out the contents. The theory of infection through the skin has had careful attention and it is only in a small proportion of cases that likely spots of entry have been discovered. The natives with naked legs get enlarged glands in the groin in about 66 per cent. of cases, but those who cover their feet and legs get the glands in the groin enlarged in about the same ratio. Moreover, the inguinal glands are affected as often as the femoral. The bacilli are seldom *found in the blood* except a few hours before death. As the buboes suppurate in a very large proportion of cases and many cases die from pyogenic infection the *object of opening* the buboes when softening (from sloughing or suppuration) has occurred is to diminish the dangers of other poisoning. Plague cases that live long enough for the glands to suppurate seldom or never die from plague. The plague bacilli seem to disappear from the glands under the influence of sloughing or suppuration. There is more to be said against Dr. Müller's theory than for it. The bacilli are probably localised at first and the toxin of plague is derived from the local manufactory and may or may not kill of itself. Pneumonic cases have not the bacilli so localised and are almost invariably fatal. When the bacilli for some reason become generalised the case is probably without doubt fatal, although it is conceivable that some subjects may have sufficient resistance to overcome even this invasion.

Dec. 24th, 1898.

ABUSE OF THE IRISH MEDICAL DISPENSARIES.

(FROM OUR SPECIAL COMMISSIONER.)

IN dealing with the new Irish Local Government Act in THE LANCET of Jan. 7th details were given concerning the appointment of the dispensary medical officers who throughout Ireland attend on the poor. The selection of these officers, based on religious and political views rather than on the technical competence of the candidates, is a grievance which affects the public interest, though the public manifest very little concern in the subject. It is to their advantage that the best men should attend to the sick and to the sanitation of the district, for the dispensary medical officer is generally also the medical officer of health. The elections, however, as already fully explained, are not contested on this basis. But whatever fault may be found with the method of selection the dispensary medical officer when appointed should be treated with common humanity and common fairness. This, however, is often not the case. The work which he has to do is frequently so heavy as to be almost beyond endurance. It is not so much the number of patients who have to be seen but the enormous distances that have to be gone over in all weathers. The ground is rough and the cottages may be dotted about amid hills and mountains. A Local Government Board report sets forth that some of these districts measure 25 × 12, 18 × 13, 25 × 10, and 21 × 11 miles. These are, of course, the largest districts—those in which the population is most scattered and sparse. Other districts are not half of the size. The dispensary medical officer generally arranges to be in attendance in different parts of his district on certain days of the week. At these centres he has a dispensary cottage or, in any case, a room kept ready for him to receive the patients who live in the neighbourhood. These are as it were out-patients; they come to him not at his home, but to the dispensary cottage in their part of his district. Such patients are bearers of white tickets and constitute probably about 80 per cent. of the total number of cases. They need not be seen at their own homes or at other than the appointed hours. When, however, a red ticket is presented to the dispensary medical officer he is obliged to go at once to the patient's house, however far that patient may live or, whatever the hour of the day. No matter what private business he may have the dispensary medical officer must put all aside to attend to the red ticket. All his other and paying patients must be neglected so as to obey the red ticket summons. As one dispensary medical officer put it to me, "Why, I should have to abandon the Lord Lieutenant himself rather than keep the owner of a red ticket waiting."

The distribution of these red tickets which thus hold the dispensary doctor in a state of thraldom naturally constitutes a precious power of patronage. The dispensary committees have not only the appointment of the dispensary medical officer, but as they are the principal distributors of the tickets, white and red, the members of this committee likewise decide who shall be his patients. As many of the dispensary committee-men are roadside shopkeepers and publicans the distribution of tickets entitling the holder to medical advice and medicine free of charge is most useful to these tradesmen. It enables them at the cost of the medical officer to render a service to their customers. The Poor-law regulations say that the dispensary medical officer must attend any poor person who has received such a ticket, but though petitioned on the subject over and over again for the last forty years the Poor-law authorities have persistently refused to define what constitutes a poor person. Thus if a farmer in a good position, with several hundred pounds in the bank, sends to his grocer for a ticket for his child it is easy to understand that the grocer would not refuse the ticket on the ground that the farmer is not a poor person. The farmer undoubtedly is not a poor person, but the grocer knows that he is a good customer and that is by far the most important consideration. It is not the grocer's business to defend and protect from abuse the professional interests of the dispensary medical officer, but it is his business to sell his groceries and with this in view he would not fail to oblige a customer. With the publican the same arguments apply as with the grocer. He has also his customers to oblige. So much is this the case and so frequent are the demands for tickets that he often leaves a blank ticket book in the hands of his potboy, a youth often sharp and vivacious but who is still less likely to trouble himself about the position and economical interests of the medical profession. Under such circumstances no trouble whatever is taken to prevent abuse. Most of the well-to-do cottage farmers are on the rates as dispensary patients. In certain districts there is absolutely no private practice of any description whatsoever. Farmers who have ample means issue tickets for their own children. The dispensary medical officer, practically speaking, has no redress. In theory, when he finds that a patient can pay he may bring the matter before the next meeting of the dispensary committee and they have the power to cancel the ticket. This sounds plausible, but though the committee should meet every month it frequently does not come together for three or four months and by that time the patient in all probability will be either dead or convalescent. Then the meetings of the dispensary committees are often most unbusinesslike and informal. They sometimes consist of a little conversation held between committee-men by the side of a car or standing under a hedge. If the medical officer has a case of abuse he must find out the precise car or hedge where his committee-men are meeting, and in such an uncomfortable position they are not likely to listen to any lengthy exposition of grievances. Besides, what is there in common between the thoughts and work of the small farmer, of the grocer, the publican, the village huckster, and the members of the medical profession? Yet these are the class of men who constitute the dispensary committee and who appoint the dispensary medical officer, and if the latter has a complaint to make he must bring it to the notice of the very persons who have committed the abuse. It is not likely that the committee will blame one or more of their own members.

The financial is not the only side of this question of abuse. Sometimes a dispensary doctor is called away from his home out of sheer malice. A rancorous committee-man can destroy the medical officer's professional life. If the latter is a poor man his committee may tyrannise over and humiliate him on innumerable occasions. A common method of destroying a medical man's peace is so to contrive the distribution of red tickets that he can never remain at home. Boys with red tickets are set on watch. No sooner has the medical officer returned and is about to sit down to his dinner than a boy enters and presents the red ticket. If the practitioner does not set forth at once there are enemies watching who have timed the entrance of the boy to deliver the ticket and the departure of the medical officer to see the patient. Perhaps the patient lives in some distant village. Then when the medical officer has returned home from the long journey another red ticket from the same village is delivered to him. He might have seen both patients at his first visit to the village, but great care is taken so to time the delivery of the tickets as to compel him to do the journey twice over. It will easily be understood that with the exercise of a little ingenuity and a great deal of malice a committee-man by the issue of red tickets could render the dispensary medical officer's life quite unbearable and this I am assured has been done more than once.

Nor are such abuses confined to rural districts. One of the Dublin dispensary doctors complained to me of the distribution of tickets by whisky-sellers. He found also that tickets were given to servants in the employ of wealthy families and these were a class of patients for whom at least a small payment could be made. Among his dispensary patients he had the wives and families of several coal-dealers. These people often looked poor enough though the husbands would be making from £2 to £3 a week. The wives, however, frequently got only about 10s. a week on which to keep house and hence the squalor and the readiness with which they obtained dispensary tickets. But why should medical men have to attend gratuitously on the families of men who spend nearly all their money on drink? In his opinion, at least a quarter of the red tickets issued in Dublin constituted cases of abuse.

An absurd theory was propounded by the Irish Local Government Board that the dispensary medical officers were not entitled to the same consideration and similar pensions as other civil servants because they did not give up their whole time. This is a great fallacy. It is the ordinary civil servant rather than the dispensary medical officer who does not give his whole time. He has his office hours but afterwards he is absolutely free and his own master. Not so with the dispensary medical officer for he may be called out at any time of the day or night. The dispensary medical officer who was describing this situation to me related how on one Christmas day he was called out three times to see three different patients who were in each case suffering from typhus fever. At the same time this medical man told me an anecdote concerning the dispensary medical officer at Markethill in the north of Ireland. This medical officer was ill when a messenger came and offered him two guineas to go to see a patient who lived at a considerable distance. He replied that he was too ill to go out and that he preferred to lose the two guineas rather than to run the risk of aggravating his condition. The messenger replied that he would have to go all the same. The patient thereupon procured a red ticket, and as the practitioner could not obtain a medical certificate entitling him to refuse his services he had to go though in so doing he risked his life and (as the patient had now got a red ticket) could not claim the two-guinea fee which had been previously offered but was obliged to attend the patient for nothing. The legend that Irish practitioners will not see any patient unless they receive a guinea fee has done much to destroy the sympathy which would otherwise have been felt for the dispensary medical officers. But it should be understood that this guinea fee covers several visits and is therefore not an extravagant charge. Nevertheless it provides many people with a pretext to go about begging for dispensary tickets; also there is often a singular want of pride among many people and they do not seem at all to object to account themselves paupers if they can save even a small sum of money.

On Nov 6th, 1896, Sir William Thomson, when president of the Dublin Medical Association, headed a deputation in the interests of dispensary medical officers which waited upon the Chief Secretary for Ireland. All the medical licensing bodies were represented. Mr. Gerald Balfour then said that the desirability of giving dispensary medical officers a pension was recognised in principle but that the precise method of so doing had not been settled. In England medical men worked for very low fees. In Ireland medical men claimed a guinea fee and this must be altered before the red ticket system could be reformed. Then the Government had to take into account that in spite of the hardships endured by the dispensary medical officers there were plenty of medical men who eagerly competed to obtain such posts. Mr. Balfour would like to see them better paid but he did not know how he could interfere with the local authorities of Ireland. Mr. Morley and other Chief Secretaries for Ireland have answered similar petitions in the same manner. It is the stock reply duly prepared by the Irish Local Government Board and reproduced on suitable occasions for the use of either Liberal or Conservative Chief Secretary. Party politics make no difference in the unsympathetic attitude of the Irish Local Government Board towards the medical profession. The Chief Secretary for Ireland whose tenure of office is but temporary and as insecure as the fate of the party to which he belongs knows little or nothing about these matters. But the Irish Local Government Board is a permanent institution and these grievances have been brought before it over and over again. The Board itself should have made proposals for reform. Sir

William Thomson mentioned a district which measured a hundred square miles where there was but one dispensary medical officer and he was seventy years old. He could not retire, for the population was so poor that it was impossible to get any private practice. These are facts well known to the Irish Local Government Board, but that Board has never moved in the matter. The policy seems to be not to deal with any question unless absolutely forced to do so, and unfortunately the medical men in Ireland are lacking in cohesion; they do not work together as a body. Such efforts as have been made to unite the profession have so far failed and therefore there has not been a strong enough pressure brought to bear upon the Irish Local Government Board. While the medical men are content to submit to unjust treatment the Government will not go out of its way to redress the grievances of the dispensary medical officers.

The reform which many medical men themselves desire is that the dispensary medical officer should become a civil servant in the employ of the Government and not of the local authority. Candidates should be subjected to a special examination in regard to public health questions and as to their capacity to act as surgeons for the police, the prisons, the bridewells, the coastguards, &c. These functions added to the duties of dispensary medical officers would constitute a fair total income, making it worth while for high-class men to apply and to qualify for the special duties. As it is the local authorities only pay half the cost of the medicines and the salaries of the dispensary medical officers. The other half is paid by the central authority, therefore the Local Government Board of Ireland has as much right to nominate as the local authorities. If Ireland is to be civilised from the sanitary point of view it would be worth while for the Exchequer to pay more than half the cost so that the central authority could appoint men who would be competent and independent of local intrigues and pressure. This is more needed in regard to public health than in respect of the abuse by which medicine for others than the poor is obtained out of the rates. The Poor-law guardians and the dispensary committee-men are themselves often the chief offenders. They distribute both white and red medical relief tickets to their well-to-do customers and to their own families and otherwise commit abuses. They often set sanitary laws at defiance and have sometimes even been paid for their votes in the election of a dispensary medical officer. Under these circumstances these petty local bodies should be deprived of the power of nominating and tyrannising over the dispensary medical officers. They have given sufficient proof of the improper use which they make of such powers. For instance, according to the Act a medical officer should receive a guinea for attending a court in regard to a prosecution or to obtain a magistrate's order for compulsory burial, &c. But now it will be seen on referring to advertisements that the local authorities require applicants to contract themselves out of these advantages. Thus, for instance, the Rathdrum Union, Aughrim Dispensary district, recently advertised for a medical officer and the advertisement stated that the salary would be "£120 a year as medical officer and £15 a year as medical officer of health, such salaries to be taken to include remuneration for all services rendered under the Labourers Act and Sanitary Act as well as the Medical Charities Act, and the payment of a substitute when the doctor is absent owing to other cause than ill-health caught in the discharge of his duties." Again, the Sligo Union advertised for a medical officer for the Cliffoney Dispensary district. The salary was £100 and £20 more as medical officer of health, together with the usual vaccination and registration fees. Then comes this clause in the advertisement: "The person appointed must attend and give evidence in all sanitary prosecutions instituted by the sanitary authorities without any additional remuneration." It need scarcely be explained that these conditions will tend to reduce the number of prosecutions. A medical officer of health who only receives £20 a year cannot be expected to spend many days in law courts. But if he received an extra guinea for each case there might be some chance of prosecutions being instituted. As explained on a previous occasion the local authorities are, in the main, desirous of preventing any sanitary reform. The advertisements quoted above are evidence of the little concern felt in this respect and are in direct opposition to the spirit of sanitary legislation since they call upon the candidates to contract themselves out of the Sanitary Act. The Legislature, to encourage the prosecution of persons who offended against the laws of health, stipulated that the medical officer who gave evidence, &c., should receive a fee of a guinea. But the Sligo Board of Guardians sets itself above the Imperial Parliament and Government. It says that the medical officer shall not receive these guinea fees and by such an act it seems anxious to discourage instead of encourage prosecutions under the sanitary and other laws enacted for the benefit of the public health. Such advertisements should awaken the attention of the Government for they certainly suggest a desire to avoid applying the laws of the land. But they also indicate that there is good reason for not trusting these petty local bodies with the appointment of such important functionaries as the medical officers of health and the dispensary medical officers.

Then, again, in most other occupations the salary increases, but this is not the case with the dispensary medical officers and no difference is made between junior and senior officers. Thus a dispensary medical officer for a Dublin district told me that he was appointed thirty-five years ago and yet he receives to-day identically the same salary as he did on the first year of his appointment. Indeed he is, if anything, poorer, for money is now cheaper than it was when first he came into office. If, however, the appointments were in the hands of the central authority young men could be sent at first to the less important districts and as they gained in experience they might be promoted to more important and better paid districts. Thus a spirit of emulation would be engendered and there might at last be reasonable hope of seeing the public health laws applied with some show of vigour. Then when there were cases of abuse the dispensary medical officer would not depend on the local authority for redress. Even in Dublin tickets for dispensary medical attendance can be obtained from publicans or their potboys. One medical officer told me that he had to attend the family of a man who was earning £5 a week. Well paid workmen who are able to keep greyhounds for racing purposes also rank among his dispensary patients. It was of no use protesting—these people did not care. They would not even join a benefit society and pay a penny per week for medical aid. The relieving officers also gave tickets and seemed to think that they could not refuse them. Yet theoretically the person who gives a ticket for dispensary medical attendance is supposed to make an inquiry and to assure himself that the patient cannot afford to pay a practitioner's fee or to join a provident dispensary or benefit society. In view of all these facts it is evident that the system of dispensary medical aid is grossly abused, that it works most unsatisfactorily, and that sweeping reforms are urgently needed. The Irish Medical Association has brought this matter forward on several occasions, and though these efforts have met with but little success they must be continued and with even more energy.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Hospital Sunday Fund.

A MEETING of the committee of the Hospital Sunday Fund was held on Jan. 5th under the presidency of the Lord Mayor (Alderman Beale). The report showed that there was an increase in the total number of places of worship contributing, being 280 as compared with 254 in 1896, when, as now, the collections were given to the General Hospital. The gross receipts for this hospital in 1896 amounted to £4422 1*s.* 10*d.* and this year to £5245 15*s.* 8*d.* The Lord Mayor expressed the hope that the movement might be placed on a basis which would appeal in a broader spirit to the whole of the people and contrasted it with the Hospital Saturday movement. Still, it was satisfactory to know that the number of life governors and annual subscribers had been increased. It was pointed out that the expenditure of the General Hospital for the year ending Dec. 31st was £23,870, and towards that sum the committee had received £17,993, thus leaving a deficiency of £5877. They had received that day £4800, but they could only apply one-third of that sum toward the expenditure of the past year, still leaving a deficit.

Poisoning by Hyssop.

A singular case lately formed the subject of a coroner's inquiry where a pregnant woman made an infusion of a pennyworth of hyssop after taking which she died. She was stated to have been in bad health and the subject of Bright's disease It is generally believed that the plants of the order to which this belongs—the Labiatæ—have no deleterious qualities, being carminatives and antispasmodics However this may be as a rule, the medical witness at the inquest expressed his belief that the hyssop was the cause of the patient s death and the jury adopted his opinion, returning a verdict accordingly.

Electric Light at the Queen's Hospital

The out patient hall of the Queen's Hospital had the electric light service inaugurated on Jan 6th An installation of 350 sixteen candle power incandescent lights was provided and pronounced a great success In addition, all the medical and surgical officers rooms, the theatre, the chapel, and the administrative departments are fitted with the same kind of light

Adulteration of Gin

At a local police court on Jan 3rd a publican was summoned for selling gin two degrees under the proof allowed by the law The public analyst for Warwick said that he was unable to give the exact percentages of water and alcohol with the quantity of added water The report of the analyst for the county of Worcester showed that the gin was 33 45 under proof and was therefore over the maximum standard of proof allowed by law The defence submitted that the certificate should have given the percentages of water and spirit and it was therefore contended that there was no case as the certificate did not comply with that requirement The case was dismissed

The Purification of Gas

THOUGH gas is so great a convenience that even now with electric lighting on all sides the civilised world would be the worse for its extinction, it must also be said that its impurities render it a great nuisance In Manchester the large proportion of sulphur in the gas has for a long time been an annoyance and a reproach and it seems as if there were a prospect of its being still further increased A question was asked at the last meeting of the city council as to what steps, if any, were being taken to reduce the abnormally high proportion of sulphur in the gas delivered, and an ingenuous alderman said that there was no danger of the matter being overlooked "It had had the serious attention of the gas committee ever since he had been a member' However serious the attention may have been it cannot have been serious enough, for it has not removed the sulphur And then another alderman, the chairman of the gas committee, rose up in his place and said that after much inquiry they had adopted a different process of carbonisation of coal— 'the regenerator process"—which had been extremely satisfactory from an economical point of view, for they got 500 cubic feet more of gas per ton of coal carbonised "But unfortunately it brought in its train a very considerable increase of sulphur," and as according to the scientific authorities "there was only one mode of purifying the gas from sulphur, and that was by lime, they would have to adopt the lime process" He thought they would be able to get a market for the lime and "that the Ship Canal would be of use in this respect' It is to be hoped that it will not be used to poison the fish at the mouth of the Mersey It is a pity that the chemists who are great at the production of sulphuretted hydrogen, cannot find some less cumbrous method of dealing with it.

Northwich and its late Medical Officer of Health

An occurrence took place at Northwich recently which emphasises the desirability in the interests of justice and fairplay and also of the public weal of delivering medical officers of health from having their tenure of office subject to the caprice or self interest of local cliques It is reported in the *Manchester Courier* of Jan 7th that "a heated discussion took place at the meeting of the Northwich Rural Council yesterday with reference to the discharge of Mr Garstang, who for three years had occupied the position of medical officer of health of the district" The Local Government Board, having "been asked to sanction the appointment of Mr Gough wrote for the observations of the authority upon a letter received from Mr Garstang, in which he said he feared his future prospects might be damaged unless some explanation of the council's last action was afforded' The clerk submitted the draft of a letter saying that there had not been the slightest intention of casting any reflection upon Mr Garstang. After a warm debate, during which it was urged by several members "that the only reason that could be adduced for the discharge of Mr Garstang was that he had done his duty too honestly and fearlessly," it was decided that no reasons should be given—which it is quite easy to understand as there seems to have been none to give—"and the simple form of reply was accepted by 14 votes to 8" In far too many places the medical officership of health is robbed of all its value as a safeguard of the public health from its being held at the mercy of those who may consider that a regard for their own supposed interests is a higher, or at all events a stronger, motive than regard for the life or health of their neighbours It may be hoped that they are not always in the proportion of 14 to 8 over the conscientious members of the rural councils and that sometimes ignorance may be the mainspring of their actions, but however that may be the too frequent result is that if he does his duty the medical officer of health soon receives notice to quit

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS)

Opening of the New Wing of the Longmore Hospital for Incurables, Edinburgh

ON the afternoon of Jan 5th Her Grace the Duchess of Buccleuch performed the ceremony of opening the new wing of the Longmore Hospital The Marquis of Lothian presided at the ceremony and in opening the proceedings he gave a short outline of the progress of the institution The central part of the hospital, which was the first part erected was opened in 1880 The present east wing was opened in 1891 by the Duke of York and Princess May, at which time a children's ward was established The directors had been enabled to meet the expense of the present extension by the liberal bequest of Mr Peter Waddell The work of the institution had been begun in 1875 with 22 patients, now they had accommodation for 150 patients Mr J A Wenley, chairman of the house committee, referred to the history of the hospital and to the various legacies and donations which had enabled the directors to carry forward the work of the institution In addition to the new wing they had a new laundry a new kitchen, a new chapel and mortuary, and the whole building was now lighted by electric light The cost of all these improvements had been about £25 000 The working expenditure of the hospital had largely to be met from annual subscriptions and as the amount necessary for keeping it up would now be increased they would have to rely on the generosity of the public to meet this increase To carry on the new wing they would need about £600 annually in addition to their former revenue The Duchess of Buccleuch, after speaking for a few minutes, declared the new wing open Mr D M Westland, on proposing a vote of thanks to the Duchess, presented her with a small key made of Scottish gold The new wing, two storeys in height with a basement, is attached to the main building by a wide corridor of iron and glass The ground floor is set apart for phthisical patients, while the upper floor is intended for the reception of cases of cancer The kitchen premises have been reconstructed and additional rooms have been provided above the kitchen for the nursing staff The new washing houses and laundries are in a separate building and the drainage has been entirely remodelled, iron pipes having been substituted for fireclay ones The main drains and connexions are placed in subways so as to be easy of access, and the drainage subway has been utilised to give access to the mortuary buildings which are placed at the Causewayside entrance to the hospital grounds. They consist of a post mortem room-

LIST OF ILLUSTRATIONS.

Photoprints of Sections of the Spinal Cord accompanying paper on the Relationship of Some Forms of Combined Degenerations of the Spinal Cord to one another and to Anæmia (Dr. J. S. R. Russell), 6, 8, 10

Cardiac and Chronographic Tracings illustrating paper on the Heart-Radial Interval and a hitherto unknown Method of Compensation in Aortic Regurgitation (Dr. P. M. Chapman), 21, 22

Diagrams and Photoprint illustrating paper on a case of Complete Rupture of the Aorta presenting some extraordinary features (Dr. R. Petch), 85, 86

Diagrams illustrating clinical lecture on Fracture of the Neck of the Femur in Childhood (Mr. R. H. Russell), 126

Skiagram of Halfpennies impacted in the Œsophagus for five and six months respectively revealed by x rays and removed (Mr. A. W. M. Robson), 133

Full-length Photoprint of a case of Pemphigus Serpiginosus (Dr. R. Y. Aitken), 139

Ori-nasal Inhalation Tube (Mr. H. B. Beale), 154

Sketch showing details of Enterectomy and *Cœlio-colostomy* accompanying paper on Intestinal Cancer and its Treatment (Mr. J. Greig Smith), 190, 191, 192

Portrait of a case of Acromegaly and Photoprint *of the Base of the* Skull showing Enlarged Pituitary *Body in situ* (Mr. J. B. Neale and Dr. E. J. Smyth), 193, 194

Chemical Formulæ represented diagrammatically and Graphic Lines illustrating paper on Piperidine as a Uric Acid Solvent (Dr. F. W. Tunnicliffe and Mr. Otto Rosenheim), 198, 200, 201, 202, 203

Portrait of a Patient and Sketch representing Thrombosis of the Veins accompanying paper on cases of Extensive Venous Thrombosis associated with Severe Rheumatic Carditis *(Dr. W. B. Cheadle* and Dr. D. B. Lees), 203

Temperature Chart of an anomalous case of Continued Fever with Perforations of the Intestine (Dr. S. H. Snell), 253

Diagrams showing the Prevalence of Tuberculosis, Tetanus, Pneumonia, Broncho-pneumonia, and Pleuro-pneumonia, illustrating *paper on the* Effects of Drying of the Soil upon the Public Health of Buenos Ayres (Dr. J. T. R. Davison), 315, 316

Instrument for Stretching Urethral Strictures (Mr. R. Harrison), 319

Diagrams accompanying paper on Pregnancy simulating Pedunculated Fibroid (Dr. E. P. Thurstan), 322

Photoprint showing Cartilaginous Mass in the Adenoid Tissue of the Tonsil and Photomicrographs of Sections of a Nodule, described in paper on Cartilaginous and Bony Nodules in the Tonsil (Dr. H. Walsham), 394, 395

Separate Plate containing six Illustrations showing the Microbe of Pictou Cattle Disease, *Sections of Liver of Cow*, Rabbit, and Human Subject and Diplococci found in the *Human Liver in* Progressive Cirrhosis, accompanying paper on the Bacteriology of Progressive Cirrhosis *of the Liver* (Dr. J. G. Adami), 396

Diagram of Operation of Gastrostomy accompanying paper on Gastrostomy *performed* by the Kader-Senn Method (Mr. A. E. Maylard), 476

Apparatus for the Treatment of Fracture of the Patella (Mr. H. Bigg), 481

A new pattern of Uterine Replacer (Dr. F. J. Hicks), 483

Diagram showing the appearance of Coccidia in the *Mosquito* as described in paper on the Rôle of the Mosquito in the Evolution of the Malaria Parasite (Surgeon-Major R. Ross and Dr. P. Manson), 489

Section of Spinal Column showing Partial *Destruction of* Vertebræ accompanying paper on Modern Methods of Treatment of Caries of the Spine (Mr. Noble Smith), 549

Drawings of Five Instruments *contained* in Wire Suture-case (Mr. T. S. Carter), 558

Photoprint of an Embryological Curiosity (Dr. J. R. Macmahon), 687

A New Aspirator *(Dr.* W. Catto), 695

Five-shilling Stamp of the Prince of Wales's Hospital Fund, 709

Chart showing the Influence of Malaria in modifying the Temperature of Typhoid Fever (Dr. F. Arnold), 773

Three-way Cock for administering Nitrous Oxide Gas and Ether, for Use with Clover's Inhalers (Dr. J. A. Codd), 811

Improved Aseptic Hypodermic Syringe and Case (Dr. E. M. Jenkins), 811

New Catheter Dish (Mr. H. de P. B. Veale), 811

Modified Uterine Sound (Mr. A. Duke), 812

New Anæsthetic Bottle, 812

Diagrams of the Limbs and their Joints in the Horse and the Human Subject illustrating paper on the Influence of Position in Fractures and Dislocations *(Dr. E. M. Corner)*, 859, 860, 861

Diagrams of the Thorax and Abdomen accompanying paper on a case of Cancer of the Pylorus (Dr. J. M. Clarke), 866, 867

Surgical Dressing Table (Dr. H. W. G. Macleod), 939

Plans of the Thompson-Yates *Laboratories* of Physiology and Pathology, University College, Liverpool, 954

Drawings of Hand and Arm showing a case of Hysterical Contraction of *the Forearm* successfully treated by Suggestion (Dr. S. K. Mullick), 934

Skiagram of Normal Chest and Skiagram of Chest of Chronic Pulmonary Tuberculosis showing Cavities at both Apices, described in paper on the X Rays in Diseases of the Chest *(Dr. H.* Walsham), 989

New Urethral Syringe (Mr. R. Stoney), 933

New Dressing Tray (Mr. S. Grubb), 938

Cutting Forceps for Use in the Treatment of Laryngeal Phthisis (Mr. R. Lake), 1068

Full-length Photoprints of a Child accompanying Description of a case of Chronic Infantile Meningitis with Basal Drainage (Dr. W. Overend and Mr. W. F. Cross), 1107

Drawing of Skull and Photoprints and Microphotographs of a Tumour *accompanying* Description of Uncommon Cases of Operation on *the Brain* (Mr. J. H. Nicoll), 1114, 1116, 1117

Graphic Curves illustrating the occurrence of Rheumatism in Children subsequent to an Attack of Chorea (Dr. F. E. Batten), 1195

Photoprints of Feet and Legs accompanying paper on a New Method of Restoring the Absent Function of Muscles in Infantile Paralysis (Mr. Noble Smith), 1196, 1197

Radiogram showing Deformity of Head of Tibia resulting from Fracture (Dr. L. Molloy), 1193

Full-length Photoprint of Patient presenting Extreme Deformity of the Lower Extremities (Mr. W. H. Battle), 1200

Metal A.O.E. Inhaler with a Simple Means of varying the Air-supply (Dr. W. J. McCardie), 1208

Amputation Retractor (Dr. F. W. Collinson), 1209

International Monument to Hans Wilhelm Meyer erected in Copenhagen, 1231

Graphic Curves illustrating Changes in Excretion of Urea and Nitrogen described in paper on Myxœdema and Allied *Disorders* (Dr. W. M. Ord), 1248

Lithotrite, Aspirating Catheter and Stylet described in paper on the Surgery of Stone in the Bladder (Mr. R. Harrison), 1254

Photoprint of Ileo-cæcal Junction and Appendix illustrating article on Acute Ileo-cæcal Intussusception (Mr. J. H. Ray), 1253

Saw for Removing Plaster-of-Paris and Other Casings, 1274

Graphic Curves showing Hourly Excretion of Urea by a Woman whose Stomach had been completely Removed (Dr. Carl Schlatter), 1317, 1318

Combined Tongue Depressor and Thermometer *Case* (Mr. J. D. Gabe), 1311

Hydrocele Injection Apparatus (Dr. Cuthbert Bowen), 1341

Aseptic Female Catheter Stand, 1341

Portrait of the late Surgeon-General W. C. Maclean, C.B., 1361

Eight Drawings of Apparatus employed in the Treatment of Neuralgia and Rheumatism by Currents of Hot Air (Dr. W. Taylor), 1385, 1386, 1387, 1388

Portrait of Patient illustrating paper on the Cure of Left Carotid Aneurysm by manipulation (Mr. R. Slocock), 1389

Statistical Diagrams illustrating the Result of the Treatment of Diphtheria by Antitoxin in *London compared* with that in Paris and Berlin (Dr. L. Cobbett), 1459

Drawings illustrating paper on the Mosquito and the Malaria "Parasite" (Lieut.-Col. E. Lawrie), 1468

Improved Form of Axis-traction Midwifery Forceps (Dr. G. P. Mathew), 1484

LIST OF ILLUSTRATIONS—(*Continued*).

New Pattern of Tourniquet, 1484

Improved Ormsby Inhaler with Attachments for the Administration of the A C E. Mixture or Chloroform (Mr. C. C. Braine), 1485

Eight Temperature Charts illustrating Paper on Reactions in Cases of Wounds and Ulcers treated by Oxygen Gas (Mr. G. Stoker), 1545, 1546

Improvements in Crutches, 1558

Nasal Curettes (Dr. G. H. Mackenzie), 1558

New Parallel Expanding Rectal Speculum (Mr. J. MacMunn), 1558

View of the Dental Hospital of London as it will appear when completed, 1573

Various Illustrations accompanying the Morison Lectures on the Relation of the Nervous System to Disease and Disorder in the Viscera: (1) Photoprints showing Nerves from the Body of the Uterus of Pregnant Cats and Nerves in the Apex of a Heart; and (2) Pulse Tracings under Various Conditions (D *Morison*), 1614, 1690, 1751, 1753, 1754

Seven Full length Photoprints of Patients, Sketch of Saw, and sev Diagrams illustrating paper on the Prevention and Correctio Short Leg in Hip Disease (Mr. R. Jones), 1624, 1625, 1626, 1627

The "Perfect" Hot Appliance, 1643

Atmo-thermo Steriliser, 1643

Portrait of the late Sir William Jenner, Bart., 1674

New Form of Warm Dry Air Inhaler (Mr. A. Duke), 1711

The "Association" Vaccinator, 1770

View of a Closet or Privy in Belfast accompanying paper on *Epidemic of Typhoid Fever in Belfast* (The Special Commissio of THE LANCET), 1812

END OF THE SECOND VOLUME FOR 1898.

PRINTED and PUBLISHED by the REGISTERED PROPRIETORS at No. 423, Strand, and Nos. 1 and 2, Bedford street, Strand, in the Paris

5. Whether the applicant is entitled or able in the circumstances which have arisen to look to any other source of assistance; and if so, what is the expected nature and extent of such assistance.

6. Whether the applicant is receiving, or has received during the past six months, pecuniary aid from any Medical Charity.

7. State how the applicant is qualified to receive assistance; vide regulation* on first page.

8. Particulars of:

Applicant's age

Number in family

How many are self supporting

How many are partially dependent

How many wholly dependent

Applicant's Signature

Address

Date

THE LANCET.

LONDON: SATURDAY, JANUARY 7, 1899.

THE opening of a New Year reminds us that it is well sometimes to congratulate ourselves on the advantages of our time, to take stock of the past, and to make some preparation for the future. Nothing is stationary about us. The art we practise is not the same art as our immediate predecessors practised; it is not even the same art as the older members of the profession still with us learned in the schools and for a time practised. The change is so great and so fundamental that we are apt to overlook and undervalue what was really good and valuable in the older practice. The rapid multiplication of remedies and of therapeutical preparations is of itself confusing and it is not altogether a healthy sign. With every desire to keep up with research and the most advanced science we have always to remember that we are practitioners. Our help must be ready and practical. Our business is to deal with disease and its practical points in practical ways. In this light it is possible, not indeed to overrate the value of research, but to underrate the value of experience and of such close clinical observation of disease and its treatment as must be possessed by every good practitioner and teacher of medicine. The chief desideratum is a better understanding between men of research and men of practice. At present there is a wide gulf betweem them. But every year will tend to lessen it and to multiply men who can act as mediators between two classes equally indispensable for the advance of medicine as a science and an art. No man can now rest on what he learned before he qualified, but with a fair amount of attention to medical literature and to the labours of those who work primarily with a view to advance medicine as a science the medical practitioner is in a privileged position for watching the clearing up of those biological problems which bear on his great art and which have so revolutionised our conceptions of disease.

With these views we wish our readers a Happy New Year. And its happiness will be none the less if it is spent in getting our minds cleared of all prejudice and conceit so as to adopt an attitude of justice towards those who would place the art of medicine on a foundation of science without disparaging the teaching of those who in practice have shown readiness, wisdom, and success. The future of the profession depends mainly on the success with which its members realise the fact that they have to adapt and apply the discoveries of others to the relief of suffering, the curtailment of disease, the postponement of death. This is their *raison d'être*. No other profession can have a better one. And it is in the power of every individual practitioner—in the humblest village as in the greatest city, in every ship that sails under our flag, in the most distant of colonies—to make his contribution to the stability and the dignity of his calling.

◆

IT is evident that during the next few years those who have pinned their faith to vaccination and revaccination as a prophylactic measure against small-pox will have a hard battle to fight, not within the profession but amongst those ignorant and self-opinionated leaders of the simple and easy-going who at present are exerting such an influence for evil, an evil which will only become manifest in full degree, perhaps, a generation hence. Whilst we cannot but deplore that owing to the framing of the new Vaccination Act the law allows such a farce to be enacted as that played at Oldham, we, as a profession, must face the fact that it will now, more than ever, be necessary to study vaccination, especially so far as concerns the preparation and preservation of vaccine lymph, in such fashion that we may gradually eliminate the small proportion of danger mentioned in the report of the Royal Commission on Vaccination and do away with all possible objection to vaccination based on what may be called preventable grounds. Assuming that vaccination is essential to the prevention of small-pox on the one hand, and on the other that some of the dangers mentioned by the Commission are real and demonstrable, it becomes the duty of every medical man, by careful observation of his patient, by refraining from vaccinating unhealthy children, and by paying attention to the source of the lymph used, to keep down what are sometimes called "accidental dangers" to a minimum. With all this, however, there are certain difficulties with which it is impossible for the practitioner to contend and in which he must appeal for guidance and help to those who are engaged in special study of the subject.

The danger of taking vaccine lymph from unhealthy or actually diseased children, though often greatly exaggerated, is one which the Commission could not ignore and so deeply were they impressed with the necessity of having vaccination without even the appearance of evil and, above all suspicion, that their recommendation of the use of glycerinated vaccine lymph taken from healthy calves came as an additional argument in favour of thorough and repeated vaccination. If now there is to be a struggle between the civil powers and those who are misguided enough to assume that by repeated iteration of their opinions they will alter the position of the vaccination question it behoves us to be prepared with all the evidence which we can command in favour of the use of pure calf vaccine lymph. One of the principal objections raised to the use of calf lymph is that in certain cases an attack of erysipelas or of erysipelatous inflammation has been the direct outcome of vaccination with this material. There can, of course, be no doubt that very frequently lack of cleanliness or other carelessness on the part of those responsible for the care and nursing of the vaccinated patient ought to be saddled with the responsibility of causing such erysipelatous attack. Allowing for all this, however, a sufficient proportion of cases of "erysipelas" assignable to the use of carelessly prepared calf lymph remains to render it desirable that steps should be taken to eliminate this possible source of danger.

Since Dr. MONCKTON COPEMAN drew attention to the now well known glycerine method of preserving and purifying calf vaccine lymph strenuous efforts have been made abroad to ensure the purity of the *vaccine lymph supply*, and in England it is generally accepted that the addition of glycerine in certain proportions is a guarantee that the lymph will in time become freed from non sporulating pathogenic or septic organisms of all kinds so that if it still retains its "vaccinating properties it may be looked upon as a "pure lymph and may be used with safety for the vaccination of healthy children who are kept well nourished and clean

In order to be able to speak with some degree of certainty on this question we have obtained the advice and assistance of a Special Commissioner of THE LANCET who for some time past has been engaged in making inquiries on the following lines 1 Is glycerine, in the proportion usually recommended a sufficiently powerful germicide to ensure the destruction of such micro-organisms as may find their way into the lymph as it is ordinarily collected from the vesicles of the vaccinated calf? The question of time in the action of the glycerine on the active vaccine element has necessarily to be accepted by us as being determined by the period given as that beyond which the lymph cannot be relied upon to remain efficient 2 Are there any glycerine vaccine lymphs in the market so collected and preserved that the conditions laid down by Dr COPEMAN in his report to the Local Government Board are complied with? 3 How far do the vaccine lymphs sold as "pure" come up to this description? 4. If glycerine does not render lymph free from ordinary micro organisms, what are the forms which persist most obstinately and for the longest periods?

It is evident that in an investigation of this nature many side issues and minor questions naturally arise With these, however, it will be unnecessary to deal except in so far as they have a bearing on the methods which now generally obtain amongst those who are preparing, collecting, and preserving lymph whether glycerinated or not We hope in an early number to publish some of the results which have been obtained, but for the present it is scarcely necessary to do more than point out that glycerine undoubtedly, as Dr COPEMAN has claimed exerts a marked bactericidal action At the same time it is evident that upon many of the spore bearing organisms it has little or no effect This in many ways is a most important distinction Streptococci and staphylococci are not ordinary spore bearing organisms and are therefore comparatively easily killed off, it is thus probable that so far as erysipelas is concerned the addition of glycerine to vaccine lymph will in most cases be sufficient to do away with the risk of ordinary

three or four In three other cases the number of bacteria was very small and these were all of a spore bearing type *A number of the other lymphs* contained a very considerable number of micro organisms, in some cases non spore bearing One sample of lymph was exceedingly bad, another brand was good on one occasion and bad on another, and another which was fairly good on one occasion was bad when examined a second time On careful examination of these different samples of lymph it appears that the methods of preserving the vesicle from contamination and of collecting the lymph differ in a most remarkable degree Given the possibility of the exclusion of a large proportion of the spore bearing organisms in one case, it is extraordinary that this should not be carried out in others, and leaving out of account the staphylococci and streptococci — the organisms most frequently found on the skin—it might be imagined that by taking moderate precautions in the collection of the lymph those organisms which are derived from the surrounding dust and air would not be allowed to make their way into the lymph from which it is afterwards so difficult to eliminate them If the calf houses and furniture can be kept clear of these spore-bearing organisms in the one case it should surely be possible to do the same thing in others and until this is insisted upon we must look forward to the appearance of numerous spore bearing organisms in certain samples of vaccine lymph contributed by each company. The extra quantity of water which it is proposed to distribute would be filtered at the existing Battersea station of the Southwark and Vauxhall Company. The company has for some years wished to disuse and give up this station and has with that end in view recently completed new works at Hampton. The Battersea station was made many years ago and originally water was taken from the Thames at that point. Later, when under the Metropolis Water Act of 1852 it became incumbent on all the metropolitan water companies to obtain their supply from the Thames at a point above the tidal part of the river, the company arranged to have their intake at Hampton and conduct river water to Battersea where it was filtered before distribution. Under the new arrangements it became, of course, preferable that water should be filtered near the intake and away from the smoke of London. The land at Battersea had also increased very considerably in value and it seemed certain that the sale of land there would go far towards providing the capital necessary to carry out the new and improved arrangements at Hampton. The new work being completed it happens at the present time that the Battersea station is no longer required for the wants of the Southwark and Vauxhall Company. It was therefore possible for the company during the present year to supply the East London Company with a considerable amount of water daily during the drought. It is now proposed to extend the life of the Battersea station for an indefinite time and to make mains from Battersea connecting the works there with the various reservoirs and mains of the other metropolitan companies. A new main passing from Battersea to Campden-hill would communicate with the reservoirs of the West Middlesex and Grand Junction Companies. Another main passing southwards to Brixton would supply the Lambeth Company and other mains would supply the New River, East London, and Kent Companies. Through these new mains and through those which belong to the various companies it would be possible to provide any company which was in temporary want with an amount of from 10,000,000 to 20,000,000 gallons of water daily. The East London Waterworks Company may this year require water from some such foreign source and on behalf of the scheme which we have sketched it is contended that it would be a great advantage to any company to be able on an emergency to obtain temporary supply to tide over the effects of an accident. Against the scheme it may be pointed out that Battersea is not a suitable place for filtering arrangements to be carried out and that the station should not be used longer than is absolutely necessary. From this point of view it may be contended that it is useless to go to great expense in putting down new trunk mains which may never be required. On behalf of the scheme and in reply to this objection it is urged that even if the Battersea station as it exists at present were not always used it would be a not inconvenient place from which water could be distributed through the proposed new trunk mains. Arrangements might ultimately be made elsewhere and nearer to the intake from the Thames for the sedimentation and filtration of the water which should then be sent to the distributing station at Battersea and pumped to the place at which it was required. For this purpose it would be necessary to retain only a small amount of land at Battersea for a pumping engine and the rest of the land might be disposed of.

On the assumption that the East London Company will during the present year require more water than they can obtain from their own sources it is not well in the public interest to oppose a scheme which would amongst other things ensure a better temporary supply of water to the East-end, and if the metropolitan companies are willing to incur the necessary expense it is most unreasonable from a public point of view to oppose any outlay which they consider necessary for conducting their business in the best possible way.

With regard to the detail of the scheme it may, however, be pointed out that at the present time the whole of the metropolitan water companies taken together are authorised to abstract from the Thames a larger amount of water than they find it necessary to supply to their customers. There is no reason therefore why any further authorisation for the abstraction of water from the Thames should be given to the united companies to enable them to carry out this scheme. Another point not without interest to the customers of the New River Company is that under the scheme at present suggested that Company would supply a considerable amount of water to the East London Company and in its place would receive and distribute Thames water filtered at Battersea. It is perhaps doubtful whether the citizens of London, many of whom are said to pay for their water at the price of beer, will be pleased with such a change in their source of supply.

◆

UNDER the heading of "Naval Surgery" the *Times* of Dec. 28th last contained an opportune communication from a retired Inspector-General, R.N., dealing with the surgical and medical equipment provided for that service. Owing to the progressive advance of surgical and medical science it becomes indispensably necessary that many newly-invented instruments and scientific appliances should be provided from time to time if the advantages to be derived from new medical discoveries and developments in surgical art are to be practically applied for the benefit of sick and wounded men. There is a tendency which is perhaps not altogether unnatural, on the part of the finance branches of the public service, to lag behind and to allow their scales and standards to fall short of the actual requirements demanded by our rapidly advancing progress in these respects. The subject, it must be confessed, is not without its difficulties, but we certainly think that Inspector-General WALTER REID has done good service in calling the attention of the Admiralty to the deficiencies which exist in our navy and in pointing out the prejudicial effect which these necessarily entail upon all concerned and upon the medical officers of the fleet who are, of course, keenly desirous of bringing all the resources of their profession to the service of the sick and wounded officers and men committed to their care. That nothing which can be reasonably required in this direction should be withheld is so obviously right in principle that even on the ground of humanity alone there is no need to dwell upon the point. With a view to giving effect to it the sick and wounded sailor may, in a broad and general sense, be regarded as entitled to look to the State whose servant he is to supply all his needs and to see that he shall not be dependent upon the care, conscience, and opportunities of any individual medical officer for providing him with the latest applied results of medical or surgical science. The survival in the present age of any antiquated system to the contrary is an anachronism. That a too rigid system of economical administration has been hitherto pursued in regard to the Naval Medical Service seems probable and was, at any rate, commonly believed. Be this as it may, however, we entirely concur with Inspector-General **REID** in absolving the present Director-General, Sir **HENRY NORBURY**, from any responsibility in the matter and hope that it may be his good fortune to inaugurate during his official *régime* some more liberal and efficient system than that which he found when taking up the direction of the Naval Medical Service. The supply of surgical instruments to medical officers of ships is not, perhaps, an easy matter to elaborate, but we have no doubt that attempts will be made in this direction. As regards the Roentgen ray apparatus it would be easy, we think, to establish a school at Haslar for the special instruction of medical officers in its use and when this knowledge had been acquired, which is soon done, to supply shore establishments at home and some of the large hospitals abroad with the apparatus. Concurring generally, as we heartily do, with the object and spirit of Inspector-General **REID'S** communication it nevertheless contains a few points which are open to comment. All naval hospitals are, we believe, equipped with instruments and appliances of various kinds on an even more liberal scale than those of the army. The position of the naval medical officer on board his ship is very much the same as that which the surgeon of a regiment occupied when the regimental medical system was in force and it is only fair to observe that he has to provide his instruments at his own cost and so has every private practitioner on commencing practice. We do not say, of course, that the cases are to be taken as quite parallel, for, as we have already contended, we hold that in the interest and for the efficiency of the public service the Government, and not the medical officer, should provide what is necessary for the care and treatment of its own servants when sick or wounded in its service.

Annotations.

"Ne quid nimis."

EPSOM COLLEGE.

CHRISTMAS DAY is past and gone, but the Christmas season is yet with us. There are many demands still remaining upon the purse, some met all unwillingly in the shape of rates and taxes, some met to the utmost extent of the charitable man's purse, such as those which deal with doles to the sick and needy. Of the many charitable institutions scattered throughout the land there is none, we maintain, more worthy of support than the foundation of Epsom College. We do not refer simply to the foundation scholars but to the pensioners. These two foundations, to quote the words of the treasurer's letter to the *Times* of Dec. 27th, 1898, "deserve the support of all members of the community considering how unweariedly medical men labour for rich and poor, always exposed to danger, beset with grave anxieties, and not infrequently losing their lives in the discharge of their calling." The two foundations support fifty pensioners, either medical men in distressed circumstances or the widows of medical men, and fifty scholars, sons or orphans of medical men, at a cost of £6000 per annum. There exist for this good work practically no secured investments and the income is mainly dependent upon subscriptions and donations. A subscription of one guinea constitutes a governor for one year, a donation of £10 10*s.* makes the donor a life governor. Subscriptions may be sent to the secretary at 37, Soho-square, or to the treasurer, Dr. C. Holman, 26, Gloucester-place, Portman-square, W. The support of this charity is a matter which we have no hesitation in bringing before our readers. It is one for the benefit of our own profession, and in charity as in everything else the proverb holds good that God helps those who help themselves. The rich among us can do much and those not so well off can do a little. If those not connected with our profession see us ready to help our brethren in distress they will be all the more likely and willing to contribute of their superfluity.

THE PREVENTION OF CONSUMPTION.

THE sanitary authorities of Liverpool and Manchester are well to the fore in attempting to carry out some of the projects suggested by the National Society for the Prevention of Consumption and other Forms of Tuberculosis. At the last monthly meeting of the Sanitary Committee of the Manchester Corporation, Mr. Alderman Walter Smith presiding, a deputation was introduced representing the Manchester and Salford Sanitary Association who urged upon the committee the desirability of steps being taken to reduce the mortality arising from tuberculous disease. The deputation included several prominent medical men, some of whom expressed their views as to the steps which should be adopted to induce the community at large to help in the prevention of a "preventable disease." The members of the deputation laid special stress upon the value of segregation. They maintained that the establishment of sanatoria for dealing with cases of phthisis in addition to the direct therapeutic advantages which would be derived might do much in the way of education because they might become teaching places, as it were, where people would be taught how to deal with the causes of infection when they returned to their homes. We think that this is a point upon which hitherto sufficient stress has not been laid, for it is only by interesting and instructing the general community that any advance can be made towards combating tuberculous disease. Some of the speakers laid emphasis on the necessity of bringing phthisis into the same category as other infectious diseases, which would therefore mean notification. To this we most strongly demur. The social results would be deplorable and the enormous number of cases occurring daily would make such a proceeding practically impossible. Not only so, but the difficulty of detecting early cases would be immense. For unless notification were thoroughly carried out the measure would be useless, and every physician connected with a chest hospital knows that the early cases coming under treatment bear a small proportion to the total number of cases, especially amongst the men. The working classes are of necessity obliged to continue at work as long as possible, and the onset of pulmonary tuberculosis is so insidious that the patient will not apply for medical advice until the disease is fairly well advanced, consequently all such cases would escape notification for many months. With a speaker who took advantage of a smoking concert at the Breck-road Branch of the Working Men's Conservative Association at Liverpool to explain in simple language the means of spread of tuberculosis we are more in accord, for he dwelt mainly on the milk-supply and the importance of the superintendence of cattle, and we sympathise with the complaint embodied in the words "although tuberculosis is the principal cause of death in this city [Liverpool], the local authorities have no power to prosecute the vendor of the disease or insist upon the separation of diseased cows from healthy animals."

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

THE honorary secretaries of this Fund have issued a tabular statement of the awards granted during the year 1898. A short account of these awards has already appeared in the daily press and the method and scope of the distribution do not seem to have met with unqualified praise. The report states that only those hospitals lying within a radius of 7 miles from Charing-cross which applied for grants within the stated time in answer to the advertisement inserted in the metropolitan journals have been assisted by the Fund. In all 46 hospitals received grants and 12 others applied who did not receive them. Besides these 13 convalescent homes received grants. Of the metropolitan hospitals with medical schools attached two, namely, St. Bartholomew's and St. George's, received nothing. On looking at the published details of the grants (the report will be found in another column) it would seem that some of the hospitals aided will not be very much better off—so far, that is to say, as regards their financial position—for in many cases—e.g., the Hospital for Diseases of the Chest, Victoria Park, the Great Northern Central Hospital, and the North London Hospital for Consumption—the grant is made conditionally on the opening of beds now closed, and in one case, that of the Female Lock Hospital, that the amount necessary for the reconstruction of the drainage of the hospital be provided for as soon as possible, from which we may presume that the grant from the Fund—a sum of £500—is not to be used for this purpose. In our opinion it is of some importance for a hospital to be in a solvent condition, unless, indeed, this would deprive the institution of the power of making the appeal *ad misericordiam* which a load of debt supplies. The distribution of money is, however, always a thankless task. There are always undeserving establishments as well as undeserving individuals and they are both apt to think that they are the contrary. But all the same we give the managers of the Fund every credit for a painstaking effort to make a worthy distribution.

THE NEW YEAR HONOURS.

THE selection of names in the 'honours' list for the New Year is so varied that it is not likely to be anything else but popular. Of the rewards to members of the medical profession a baronetcy goes to Sir Henry Thompson, F.R.C.S. Eng., whose work in the domain of surgery and especially that of the bladder is well known to the profession. As President of the Cremation Society he has done not a little to popularise cremation as a method for the disposal of the dead. Dr. Hermann Weber, F.R.C.P. Lond., who is a well-known authority on climatology and balneology, receives a knighthood, as does also Dr. G. Plunkett O'Farrell, Commissioner of Control and Inspector of Lunatic Asylums in Ireland. Sir Charles Cameron, M.D. Dub., is to be made a Companion of the Bath, an honour which is well deserved. Mr. R. U. Moffat, M.B., C.M. Edin., Principal Medical Officer of the Uganda Protectorate in East Africa, and Mr. J. S. Macpherson, L.R.C.P. & S. Edin., also of the Uganda Administration, are to be made Companions of the Order of St. Michael and St. George. Colonel William Pleace Warburton, M.D. Edin., I.M.S., and Colonel David Sinclair, M.D. Aberd., I.M.S., receive Companionships of the Order of the Star of India, and Lieutenant-Colonel Henry Kellock McKay, M.R.C.S. Eng., I.M.S., and Major Winthrop Benjamin Browning, L.R.C.P. & S. Irel., I.M.S., Companionships of the Order of the Indian Empire; Captain John Lloyd Thomas Jones, M.B. Durh., I.M.S., Captain William Ernest Jennings, M.B. Edin., I.M.S., Captain Arthur Frederick William King, M.R.C.S. Eng., L.R.C.P. Lond., I.M.S., and Lieutenant William James Niblock, M.B. R.U.I., I.M.S., are to be enrolled as Honorary Associates of the Order of the Hospital of St. John of Jerusalem in England. It is noticeable that the greater proportion of medical honours go to members of the Indian Medical Service, but it must be remembered that the Soudan honours have only recently been issued when the British medical service did not go unrewarded. This large military proportion, we think, shows the increased attention which is being paid to medicine in army matters and reflects in a large measure the great military strength of our empire.

THE LANCET RELIEF FUND.

THE report made this year by the Almoners of this Fund, founded as it is upon the accounts of the tenth year of its operation, suggests very naturally a somewhat more extended review than that of the period of twelve months which comes directly under observation. The year itself repeats in a striking manner the features to which we last year drew attention as being salient and satisfactory points in the experience of the charity. That is to say, it is again a notable feature of the report that the benefactions show a reduction both in number and amount, a circumstance from which it seems to be a fair inference that the pressure of necessity upon those of our professional brethren who have fallen upon evil times has been sensibly less acute than in some recent years. The experience of a single year would seem to afford but a slender basis for any general conclusion of this sort and it is therefore very pleasant to be able to point to a sequence of two annual reports tending to the same conclusion. When, moreover, it is borne in mind that the same period of time has been marked by many signs of general prosperity it is reasonable to take a sanguine if not confident view that the diminished stress is not more apparent than real and that the flood tide of a prosperous time has found its way even into the shallows where adversity is at home. Taking, however, the wider survey which is suggested by the close of a decade we note as matters of some special interest the figures which serve as indexes to the character of the charitable work to which the Fund has been subservient. Chief among these are the items which denote the sums granted by way of loan and by way of gift respectively. Out of a total of £2899 12*s.* distributed the sum of £1787 2*s.* has been given out-and-out, the balance of rather over £1100 having been nominally lent. We say nominally lent because it is found in many cases that the borrower is not able to redeem his promise to repay and thus a considerable proportion of the benefactions which figure as loans in the annual statements of account are loans only in name—in substance they also amount to gifts. The cases therefore which can be effectively aided by a loan are shown by experience to be fewer and to total to a less aggregate amount than those which demand the assistance of an unconditioned grant. And this is a feature which tends to become more and more pronounced. It was sufficiently marked in last year's statement to call for comment; it is still more conspicuous in the statement now under review. In this we see no matter for regret, although it must be admitted that to those who are behind the scenes and know the details of all the various cases dealt with there are none more interesting, none in which it is possible to extend the helping hand with a livelier sense of satisfaction than those in which a timely loan helps a brother overtaken by sudden adversity to help himself. That of a truth is the kind of mercy that is "twice blessed" and in the person both of him who gives and him who takes. Nor should it be forgotten that the repayments made by those who had benefited by the Fund form a most welcome addition to the resources of the Almoners and one by no means to be despised, seeing that a sum of upwards of £200 has in this way been placed at their disposal during the period now under consideration. This work, as we have before remarked, is so intimately associated with THE LANCET that we feel ourselves at liberty when writing about it to express our sincere thanks to the honorary officers—Almoners and Auditor—who have during the past year undertaken the duty of administering the Fund. Sir Samuel Wilks, Sir William Mac Cormac, and Sir Henry Pitman have in this way renewed the evidence which they have given in previous years of their interest in the welfare of the most unfortunate of our professional brethren. Sir William Turner who has been elected to the Presidency of the General Medical Council, vacated by the lamented death of the late Sir Richard Quain, has kindly consented also to assume the charitable *rôle* of an Almoner of THE LANCET Fund and has personally interested himself in the discharge of its duties. In presenting to each and all of them our thanks we assume to speak not only for ourselves as donors of the Fund, to whom its due administration is naturally a matter of solicitude, but in the name also of those who benefit by it and whose gratitude, not always articulate, is in not a few cases evidenced by expressions which it is a privilege to convey but a satisfaction largely alloyed with sympathetic sorrow to receive. The application form of THE LANCET Relief Fund will be found in our present issue and can be readily detached for use in case of need. We again take an opportunity of asking those of our readers who may have occasion to assist in furthering any application made for relief from this source to note carefully the conditions on which applicants become entitled to participate in the benefits of the Fund, as it is still found that many requests are put forward which are so far outside the objects of the benefaction that they cannot be entertained and from such applications nothing but disappointment can result. All applications should be made (in writing) to the Secretary, Mr. Edward Davies, THE LANCET Offices, 423, Strand, London.

TRUE HEROISM.

ON Dec. 28th, 1898, occurred an opportunity for one of those acts of unassuming heroism which we are proud to be able to say are not so very uncommon amongst us. In Clerkenwell Close there lives an electro-plater by name Grimme, but he was away and the foreman, Franklin, was in charge. The workshop is very small and the materials and chemicals necessary for the trade have mostly to be placed on the floor. At the time of the accident there stood on the floor an earthenware pan containing some 6 gallons of sulphuric acid and an iron pan full of cyanide of potassium. Franklin's three children were in the room and they, it is supposed, upset the vitriol which coming into contact with the cyanide immediately gave rise to a rapid evolution of hydrocyanic and carbonic acids. A boy named James Wright who was standing outside the room said he saw a thick smoke rising, noticed that two of the children had fallen into the pool of acid on the floor, and that Franklin had also sunk down. Wright ran upstairs, opened a window and called for help, after which he lost consciousness for a few minutes. On coming down he saw a soldier on the stairs. He groped his way into the room, hauled out one child by the legs, gave it to the soldier and again became unconscious. The soldier, who is a gunner in the Royal Artillery named William Hall, was going along the street when he noticed a crowd. He made his way into the house three separate times and brought out the children first and afterwards the father. The sufferers were taken to St. Bartholomew's Hospital and attended to. We have told this tale very plainly, but it seems to us that the action of both Wright and Hall is beyond all praise. Very possibly neither quite knew the danger which he was running, but anybody who has ever experienced that sensation of being gripped by the throat which the inhalation of hydrocyanic acid and carbonic acid produces will appreciate the pluck shown by these two heroes, and especially the bravery of Hall who went into the house three separate times. The crowd outside, by way of contrast, stood still, stared, and did nothing. The pluck of Hall and Wright will never be forgotten, and we hope that they will receive the Albert medal or some similar recognition of their admirable conduct.

THE NERVOUS SYSTEM IN SCLERODERMA.

IN the December number of the *Glasgow Medical Journal* Dr. Lindsay Steven publishes a lecture on a very interesting and important case of scleroderma in which there was pronounced hemiatrophy of the face, body, and extremities and in which he had an opportunity of examining the condition post mortem. A full clinical account of the case was published in the *International Clinics* in 1897. As regards the patient's condition on readmission to hospital in the spring of 1898 it need only be said that her skin on the affected side showed breaking down and ulceration, and it was on account of this and of the symptoms of an ovarian tumour—symptoms dating from August, 1897—that she sought readmission. Abdominal section was performed for the removal of this tumour but unfortunately she succumbed on the third day after operation. As regards the internal organs it need only be said that there was complete absence of pericardium, and there were *cicatrices* in the spleen and a condition of the kidneys of mixed parenchymatous and interstitial nephritis. The cortical matter of the hemisphere opposite to the atrophic side was perhaps a little thinner, but no microscopic examination is recorded. In the spinal cord, however, the grey matter of the right (the affected side) anterior horn was diminished, the ganglion cells were smaller and less numerous, and their nuclei and plasma granules were not so well defined as in the corresponding cells of the opposite side. The neuroglia also in the right horn seemed denser than in the left. Corresponding changes could not be made out in the medulla or pons. Throughout the cord, *medulla*, and pons the arteries, especially of the grey matter, were surrounded by spaces, either empty or containing a structureless homogeneous material, and most of these spaces had well-defined margins. The nerve fibres from the cervical and lumbar plexuses showed a well-marked parenchymatous degeneration. The skin showed the absence of fat, thickening of the horny layer, and atrophy of the *papillæ*. Between the papillæ and the muscles there was a thick layer of dense connective tissue. Dr. Lindsay Steven regards the atrophy of the anterior horn, the changes in the cells there, and the cavities around the vessels as of much importance and significance in reference to the morbid anatomy of scleroderma. He looks upon the condition as the result of these changes—i.e., as a trophoneurosis of central origin. The neuritis he regards as secondary and recent. The case is of much interest and its importance is enhanced by the long time—twelve years—during which the patient had been under observation. We should doubt, however, whether Dr. Lindsay Steven's explanation of the relation of the changes in the skin to those in the central nervous system will be quite satisfactory to everyone, and we should have thought it would hardly be necessary to invoke some recent parenchymatous neuritis to account for changes in the peripheral nerves. With such changes in the anterior horn cells and in the skin, changes in the nerves, both parenchymatous and interstitial, would be quite what we should expect. It would also be interesting to know the microscopical character of the changes in the cerebral cortex.

THE NEW PHYSICAL LABORATORY OF THE OWENS COLLEGE, MANCHESTER.

THE laboratory of which the foundation-stone has been laid on the twenty-fifth anniversary of the occupation of the present Owens College buildings will be the largest and most completely equipped in this country. It stands on a separate plot of ground adjoining the Owens College site and consists of a main building and a large annexe, the latter being more especially intended for electro-technical work. The principal building is 100 ft. long and over 60 ft. wide and consists of a basement and three storeys. The cost of the building with fittings and new apparatus is estimated at £30,000. It is intended to have at least one room set aside for constant temperature work and to establish a small plant for the production of low temperatures. An electro-technical laboratory will be added in which large currents will be available for electric furnaces. One of the features of the laboratory will be a carefully-planned system of ventilation combined with an attempt to exclude dust as far as possible from all rooms and especially from instrument cases. The plenum system had to be rejected because it takes up too much valuable basement space, because it is ineffective as regards exclusion of dust, and because the inevitable noise and mechanical shaking due to the fans would have seriously interfered with the work of the laboratory. The architect is Mr. J. W. Beaumont who, before finally drawing the plans, was sent by the Council of the Owens College to visit the principal modern laboratories of Germany.

VACCINATION LITERATURE AND LEAFLETS.

WE are asked from time to time where literature on the subject of vaccination can be obtained such as would be suitable for the purposes of educating the public in this matter by the aid of lectures and by the gratuitous distribution of trustworthy pamphlets and leaflets. We would refer inquirers as to this to Dr. Francis Bond, honorary secretary of the Jenner Society, Gloucester. Under Dr. Bond's supervision a series of very valuable pamphlets and leaflets has been compiled. Some are suitable for lecturers, others for issue to the public by vaccination officers, others, again, for distribution by district visitors. On this subject it is desirable to remind boards of guardians who desire that children within their jurisdictions shall be protected against small-pox andits miserable consequences that section 28 of the Vaccination Act, 1867, is still in force, and that under this section they are empowered to pay out of their funds all reasonable expenses in circulating information on the subject of small-pox or vaccination and in taking measures of this sort in order to promote vaccination. This section has always been held fully to cover the distribution of literature of this description and it would be well if public vaccinators were to urge boards of guardians to supply leaflets such as are issued by the Jenner Society to vaccination officers with a view to their distribution together with any notices which they may have to issue in accordance with the regulations governing the duties under the Act of 1898.

THE CENTENARY OF THE RUSSIAN MEDICAL MILITARY ACADEMY.

ON Thursday, Dec. 29th, at St. Petersburg the celebration of the Centenary of the Russian Medical Military Academy was opened by a religious service. The prize distribution to the successful students of the year then took place in the presence of the Grand Duke Constantine (the Honorary President of the Academy) and of the Minister of War and other distinguished men, including the Bishop of Finland and other ecclesiastics. Early on Friday morning a grand requiem service was held in memory of past Russian Emperors, patrons of the Academy. The great function of the celebration took place afterwards in the largest hall in St. Petersburg before a most distinguished company presided over by the Minister of War, the numerous decorations worn upon the brilliant uniforms of the officers and the bright colouring of the academic costumes of various nationalities giving much grandeur to the scene. Representatives from universities and scientific bodies were presented on the raised platform and offered congratulations from their respective societies. Among the British institutions which sent messages were the Royal Society, the Universities of Oxford, Cambridge, Edinburgh, Glasgow, and Aberdeen, and the Royal College of Surgeons of England. The delegates from these bodies comprised the Dean of Trinity Hall, Rev. H. S. Cronin, Professor Shipley, Mr. Owen, Mr. Cross, Professor Ogston, and Dr. Ferguson.

FRACTURE OF THE INTERNAL TABLE OF THE SKULL.

FROM *a priori* considerations we should hardly have considered it possible that the inner table of the skull could be broken without any fracture of the outer table, yet this lesion has been observed many times and Captain Standage, I.M.S. recorded an instance of its occurrence in THE LANCET of Nov. 26th, 1898, p. 1388. The earliest reference to this form of injury is to be found in a work called "De Fractura Cranii," published by Jacobus Berengarius in 1535; Ambrose Paré alludes to it also.[1] Garegeot relates a case observed by Mery.[2] Pott mentions two cases in his work "Observations on the Nature and Consequences of Wounds and Contusions of the Head."[3] Samuel Cooper described the condition in his "Surgical Dictionary."[4] W. F. Teevan[5] was the first to point out the true explanation of the greater extent of the fracture of the inner table in ordinary fractures of the skull and therefore the reason why the inner table may be broken while the outer suffers no injury. He showed that in all fractures it is the side of extension and not the side of compression which is the first to break, and when the skull is struck the outer table is compressed and the inner table is stretched. Guthrie, in his "Commentaries on the Surgery of War,"[6] describes the occurrence of this form of injury, but probably the best account is to be found in the "Medical and Surgical History of the War of the Rebellion"[7]; during that war there were 20 cases in which the inner table was broken without any fracture or depression of the outer table; in 4 of the cases trephining was unavailingly performed and only 1 patient recovered of the whole number of cases. La Motte[8] stated that a "cracked pot sound" could be obtained over the broken bone and Strohmeyer[9] found the pitch on percussion to be distinctly high. It is difficult to give any exact estimate of the frequency of the lesion for it is probably often overlooked and if the fracture gives *rise to no* symptoms recovery may occur without the surgeon recognising that any fracture has taken place. Prescott Hewett[10] found 3 cases in 78 necropsies on cases of injuries to the head; in two of these the lesion was very slight, but in the third case it was severe. He mentions that he had met with only one other case. When the question of the etiology is investigated it is found that in a large proportion of the recorded cases the oblique impact of a bullet has caused the fracture,[11] while in some the injury has been due to a "spent" ball. In a case recorded in 1880[12] the patient received a "brush" blow from the handle of a crane. Of the 20 cases recorded in the "Medical and Surgical History of the War of the Rebellion" 14 were due to the oblique impact of musket balls. It is probable that with our modern projectiles of high velocity this variety of fracture of the skull will be less frequently seen.

MENTAL CONCENTRATION UPON A PART AS A FACTOR IN THE FORMATION OF A NEW GROWTH.

IT has long been a popular idea that too much thinking about any particular part or organ may lead to disease of that portion of the body, but it must be confessed that very little substantial basis of fact has served as foundation for this superstructure. Dr. Carpenter was, we believe, the first to point out and to demonstrate by experiment that concentrating the mind on a special part of the body will lead to a local hyperæmia with sensations of tingling and itching, but, so far as we are aware, no true inflammation was ever produced. It is not difficult to understand that the directing of the mind towards some particular part of the organism may alter the blood-supply of that part and so may modify materially its nutrition. If this be possible—and who can say it is not?—it is not at all unlikely that morbid changes may result from, or be predisposed to by, these slight beginnings. It is very difficult, however, to find many cases which can only be explained satisfactorily by some such theory. Mr. W. H. Bennett, in a clinical lecture recently delivered at St. George's Hospital and published in this issue of THE LANCET, quotes two cases which if not convincing are at least very suggestive. In each of them increased growth of a tumour appeared to follow the continued concentration of the patient's attention on the part. It has occasionally happened that a physician or a surgeon who has paid particular attention to the diseases of some one organ or region of the body ultimately suffers from an affection of the same part. These cases, though striking, are but few in number and no more numerous than would be expected from the laws of probability. If there were any certain foundation for such an idea medical men might be found to hesitate before "specialising" on the more painful and unpleasant diseases to which the body is liable.

THE LIVERPOOL LADIES' CHARITY AND LYING-IN HOSPITAL.

BY a majority of 45 to 31 votes the subscribers to the Liverpool Ladies' Charity and Lying-in Hospital carried the following resolution: "That single women in exceptional circumstances who, after careful investigation by the ladies' committee, are found to be deserving objects of charity, shall be eligible for admission into the hospital for their first confinement." It was pointed out by Mrs. Henry Tate, who moved the resolution, that its terms were in accordance with *the rule which was in force at the City of London Lying-in* Hospital dealing with similar cases. She wished it to be understood that the supporters of the resolution only wished to deal with women otherwise respectable, such as shop assistants and domestic servants. They would have nothing to do with women of the profligate class and such as were familiar with the rescue homes and the nigh mission. The proposal had the approval of the promoters of the Victoria Women's Settlement, Monsignor Nugent and the Countess of Derby. The latter was eminently qualified to speak on the question as before she went to Canada she had for eight years under her supervision a home containing twenty beds, the occupants of which had all turned out satisfactorily with the exception of two. Much stress was laid upon the fact that the hospital which contains fifteen beds had only three and a half beds occupied per week, which clearly shows that the position of the poorer women had altered since the foundation of the charity in 1841. At that period the opportunities afforded for nursing these poor women in their own homes were not so favourable as at the present time. The advances made in the direction of sanitation, better wages, and cleaner houses for the working-classes enabled them to remain at home during the period of confinement in a large proportion of cases. These circumstances indicate that the objects for which the charity was initiated were to a great extent defeated by the force of changing times and that the hospital might be utilised in deserving cases for the benefit of a class largely more sinned against than sinning. The rule of a hospital which only affords benefits to less than one-fourth of the number provided for by the founders is clearly in need of modification. It is computed that 200 respectable unmarried girls are confined yearly in the Liverpool workhouses. These poor girls cannot avoid contamination from the associations with which they come in contact, thus affording an additional argument for a more humane line of treatment in the matter of admitting them to the wards of a lying-in hospital (special or otherwise as the case may be). The resolution had the warm support of Mr. William Rathbone, whose length of experience in the management of general hospitals and workhouses is probably unequalled. The change of law will involve considerable expenditure in the matter of additional beds and probably in the construction *of a new block*. Promises of contributions have already been made for these objects and the generally expressed opinion prevails that the subscribers to the charity in their new departure have acted in accordance with the charitable spirit of the age.

THE PROPHYLAXIS OF PLAGUE BY HAFFKINE'S INOCULATION.

ON Nov. 22nd, 1898, Mr. Balchandra Krishna, the President of the Grant College Medical Society of Bombay, read an interesting paper before that society on the prophylaxis of plague by Haffkine's method. The inoculating fluid is prepared by sowing plague virus in a neutral mutton broth mixed with a small quantity of cocoanut oil or ghee. When the growth is at its height the culture is heated and carbolised. It is then set aside, when the fluid separates into two portions, the one a sediment containing the remains of the bacilli, the other a limpid fluid. It is the latter which is used for prophylactic inoculations. The dose for a healthy adult male is 2·5 c.c. of a standard solution which is repeated in ten days or a fortnight. There is a good deal of reaction, the temperature rising to 102° or

104° F. with a feeling of malaise, but this subsides in twenty-four hours. Pain at the seat of inoculation lasts from four to five days and then subsides. M. Haffkine's preliminary experiments were made on rabbits. Twenty were taken, of which ten were inoculated. All the twenty were then infected with plague. All the ten unprotected died, while the ten inoculated ones lived. In the case of human beings inoculations have been made at ages varying from seventy years to ten days. Up to the present no evil results have been noticed to follow the injections. In the inoculations performed in Bombay during the first year of the recent epidemic there were three deaths which occurred within a few days of inoculation. One of these was from definite plague, one from suspected plague, and one from paralysis. The number inoculated altogether was 8142. Pregnant women do not abort if inoculated with small doses often repeated. Besides the prophylactic effect against plague the inoculation would seem to have a good result in cases of chronic malarial fever. Mr. Krishna cites the cases of Captain Macdonald, I.M.S., and his servant, who were inoculated when suffering from chronic attacks of fever with the result that the fever left them. As to the efficacy of the inoculation the instance of the Byculla House of Correction shows that it does possess a real protective effect. During an epidemic in this prison 173 persons were uninoculated; of these 12 were attacked and 6 died. Of 148 inoculated 2 were attacked and both recovered. In Damaun 2197 were inoculated and 36 died. Of those uninoculated, 6033 in number, 1482 died. Many of the tables of experiments in various districts are given and the conclusion drawn by Mr. Krishna from them is that Haffkine's process has a very real protective influence against plague. In his opinion "it is our duty as medical men to encourage it by all possible means and to induce the public to take full advantage of it."

RED CROSS EXTENSION.

IN the Students' Number of THE LANCET for 1893 we commented on the ever-enlarging field for medical science and medical practice, taking as our text the proposal made at the last International Congress of the various Red Cross associations that that great "relief organisation" should widen its scope and include not only the transport, the tendance and the treatment of the wounded on the field, but also the care of the injured in the colossal disasters so frequent in modern life—mining explosions, floods, earthquakes, railway accidents, and such like, as well as the sufferers in famines, droughts, and epidemics. Here, it was said by the authors of that proposal, we have a well-trained, amply-equipped relief service, mainly medical in its inspiration and its *personnel*—a service, moreover, completely its own master except on the outbreak of war. Why should it be idle when in time of peace a widespread, far-reaching calamity overtakes a district or a populous centre and not put its admirable organisation and working staff at the disposal of the sufferers? Advanced as a "pious opinion" and superficially discussed at the International Congress referred to (that at Rome in 1892), the proposal was seriously taken up and in great measure threshed out in the succeeding International Congress (that held at Vienna). Now, in view of the next congress of the kind the various Red Cross associations throughout Christendom have been invited to consider the best means for giving practical effect to this new development so as to contribute to the preparation of an "order of the day" which, on approval by the congress, shall thereafter become part of the programme of the Red Cross and bring the organisation into closer touch with daily life and modern evolution. Surely this is a proposal which is deserving of cordial consideration and support. The Swiss, the German, and the Russian delegates at the Vienna Congress spoke for their respective nationalities in its favour, and it is expected that at the next congress Great Britain and France will also give in their "adhesion." Italy, indeed, has long ago anticipated the proposal by her practice. Visited more than any other European country with floods and earthquakes, and with her full share of the casualties incurred by modern life, she has not scrupled to employ Red Cross service for the relief of suffering so occasioned; and, while always respecting the funded resources specially set apart for the wounded in war, has utilised the trained *personnel* of the organisation wherever on a large scale its intervention was required. She has even started subsidiary services, the "Croce Bianca" and the "Croce Verde" (White Cross and Green Cross), to render similar aid—services which, of course, will be absorbed into the greater unity of the Red Cross when once the proposed development of this latter becomes law. In Tuscany the "new departure" contemplated has been enthusiastically taken up and the leading aristocracy, reinforced by the clergy and the more public-spirited of the citizens, are founding sub-associations to fall into line with the main body on its assuming civilian in addition to military duty. Demand for increased medical assistance is one of the inevitable consequences of the movement and the War Office is affording facilities at the autumn manœuvres for the training of a more numerous *personnel*. Amid much that is discouraging, and even disquieting, in Young Italy, her alacrity to promote "Red Cross extension" is certainly consolatory and reassuring. She claims, not without right, priority in having conceived the organisation in time of war. She is laudably making it her ambition to be the first to utilise it in time of peace.

THE TREATMENT OF ANEURYSM BY THE CONJOINT USE OF GALVAINSM AND INTRODUCED COILED WIRE.

A REPRINT has been issued of a paper which appeared in the *Philadelphia Medical Journal* for Nov. 17th, 1898, by Dr. D. D. Stewart, on the above subject. After referring to cases on record which have been similarly treated he gives details of seven cases which were either under his own care or in which he was personally interested and directed the technique. The results were most encouraging, the more prominent symptoms of the disease being kept in abeyance and, as shown by the examinations made after death long periods after the operation, the fatal termination not always being due to the aneurysm, well formed and organised clot was discovered. Dr. Stewart briefly summarises the main features of the operation. It consists in introducing into the sac, under the strictest antiseptic precautions, a fine coiled wire previously so drawn that it may be readily passed through a thoroughly insulated needle of somewhat larger calibre than the wire and after introduction may assume marked spiral coils, so that, with a moderate amount of wire, the entire calibre of the sac will be occupied by wire unless the cavity be already filled with coagula or the sac be of unusual size. Silver, gold, and platinum wire are undoubtedly the preferable materials. The amount of wire required depends necessarily upon the calibre of the aneurysmal sac and must be decided upon with the greatest nicety of judgment, as with too small an amount little or no result will be obtained and with too great a quantity permanent cure through obliteration of the sac by contraction of the clot cannot be expected. The anode or positive pole should invariably be the active electrode. This is connected with the wire and the negative rheophore, a large clay plate or an absorbent cotton pad made after the method of Maney, is placed upon the abdomen or the back. Experience has shown that the current should be gradually increased in strength, finally reaching from 40 to 80 ma, and the time of application should be from three quarters of an hour to one and a half hours The solidification is rapid and is generally manifest before the end of the electrical session through changes apparent to the eye and the hand in the pulsation and in the degree of consistence of the sac wall These changes become more decided in the course of a few days, until after a time in the most favourable cases a hard nodule with a communicated pulsation alone replaces the previous expansible tumour This was the history of 4 of the 10 cases now on record

THE MEDICAL DIRECTORY THE DISTRIBUTION OF THE MEDICAL PROFESSION

LAST week we mentioned the receipt of the Medical Directory for 1899, and we now proceed to give some details of the statistics contained in this valuable work of reference The whole number of practitioners for 1899 is 34,994—an increase over the figures for 1898 of 91 a very decided drop from the increase for 1898 over 1897, when the figures were 619 The practitioners included are distributed as follows, the numbers for 1898 being given in brackets —Number of practitioners in the London list, 6117 [6081], in provincial England, 15 497 [15,400], in Wales and Monmouth, 1100 [1081], in Scotland, 3394 [3412], in Ireland, 2551 [2615], resident abroad, 3795 [3770] Naval, military, and Indian medical services, excluding those who appear also in other lists, 2528 [2521], too late list, 12 [23] The deaths numbered 532 as against 599 in 1898, though of course this number is under the real amount for the year We see that Monmouth still continues to be included under Wales and in the list of London hospitals with medical schools the extraordinary alphabetical or rather non alphabetical arrangement is retained by which St Bartholomew's Hospital is put first as "Bartholomew's (St), while St George s, St Mary's, and St Thomas s are placed under the letter S The legal and other information is given with the usual accuracy, but we think something more might have been said about the working of the new Vaccination Act, for the new order was dated Oct. 18th There is so much that is good in the Directory that we only mention these failings with the wish to see future editions yet more perfect than the present one

TUBERCULOSIS IN LAMBETH WISE SUGGESTIONS BY THE MEDICAL OFFICER OF HEALTH.

DR JOSEPH PRIESTLEY, the medical officer of health of Lambeth, has presented to his vestry a report upon the nature and preventability of tuberculosis which contains the following wise suggestions —(1) That a circular letter be sent round to all the medical men in Lambeth pointing out that the vestry is prepared to disinfect free of cost all rooms with their contents recently occupied by patients suffering from tuberculosis, which have become unoccupied owing to the deaths or removals of such patients when requested to do so by the medical men or others in attendance, (2) that a circular letter be sent to the person or persons in charge of public institutions in Lambeth pointing out the nature of tuberculosis as a disease and the importance of having means adopted for the prevention of its spread and offering disinfection free of cost by the vestry's officers where it may be necessary; (3) that a circular letter be sent to the occupiers of those houses in which deaths from tuberculous disease are reported week by week to the medical officer by the Registrar General offering disinfection free of cost by the vestry, and (4) the issuing of leaflets pointing out in simple language the danger of the disease and the ready means at hand for its prevention to clergymen, district visitors, school teachers, and such persons who from their position may be expected to have opportunities for disseminating the information We commend Dr Priestley s suggestions and the action of his vestry in promptly adopting them *in toto* If the disinfection processes supplied gratis by the vestry of Lambeth are followed by proper cleansing, scraping, and whitewashing by the owners of the infected dwelling places we may expect a notable fall in the local mortality from phthisis, while the value to the community of a supply of sound reasons why they should take precautions themselves against the spread of disease cannot be readily over estimated

MAGISTRATE AND CORONER.

OUR readers will remember that recently an inquest was held by Mr Braxton Hicks on the body of a child aged seventeen weeks Mr James Jerome Mackay, acting on the coroner s warrant (which requires an examination of the viscera head, thorax, and abdomen), examined the remains and subsequently swore at the inquest that *in his opinion* death was due to congestion of the brain, presumably basing his judgment upon facts observed at the necropsy A second examination was conducted by Mr F C Kempster and Dr L S McManus, and these gentlemen testified at the adjourned inquest that "no proper examination of the body had been made, that the brain was not congested; and that death was due to asphyxia consequent on double pneumonia" Before calling upon Mr Kempster and Dr McManus for their evidence the coroner asked the jury for their opinion of the cause of death on the grounds furnished by Mr Mackay's testimony Mr Braxton Hicks cautioned Mr Mackay who adhered to his previous statement on oath The jury eventually found that death was due to asphyxia from lung disease thus practically avowing that they could not place reliance upon Mr Mackay s version of the facts and consequently upon his opinion. Mr Mackay was charged at the South Western police court with committing wilful and corrupt perjury, the Treasury prosecuting Mr Plowden, the presiding magistrate, treated Mr Braxton Hicks who detailed the circumstances of the inquest with scant courtesy, we might even say with contemptuous badinage This was unworthy of the learned magistrate seeing that by virtue of his office Mr Braxton Hicks has statutory magisterial powers We do not agree with Mr Plowden that the proceedings at the inquest were "eccentric" or that "all the ordinary landmarks in a court of justice were absent' A coroner's court is one of first instance and procedure therein is not ruled by the inflexible regulations as to the admission of evidence prevailing in a stipendiary s court We assert that Mr Braxton Hicks did not ask for two verdicts, for the request which he preferred to the jury before calling Mr Kempster and Dr McManus was simply a means of ascertaining the impression made upon the minds of the jury by Mr Mackay s evidence Mr Braxton Hicks knew what Mr Kempster and Dr McManus would swear to, and rightly, in our judgment, he sought to emphasise what he regarded as a gross dereliction of duty Mr Plowden in discharging the case described it as a question of divergent medical opinion, but Mr Mackay was charged with perjury—that is, with falsely swearing as to facts For the purpose of the prosecution it did not matter one iota whether the medical witnesses were agreed in opinion or not The real point at issue was whether Mr Mackay had performed the post-mortem examination properly and, if not whether he had sworn that he had We do not hesitate to say that if the testimony of Mr Kempster and Dr McManus was reliable perjury was undoubtedly committed We hold that Mr Braxton Hicks was in duty bound to take the course he did It was all nonsense for Mr Plowden to say that because all the organs should have been examined "if the child died from fracture of the brain it is the duty of the doctor to inspect the toes." Were such a statement made by counsel and not by a judge we should consider it as constituting an abuse of advocacy. It is of the highest importance that medical men should carry out with exactitude and integrity post-mortem examinations which are required in order that the cause of death may be ascertained. Neglect to do this might lead to serious failure of justice and would weaken a necessary safeguard to the community.

WITH the consent of Lord Kitchener a ward is to be endowed in the new Gordon Hospital at Khartoum in memory of the late Mr. T. W. M. Longmore, M.R.C.S. Eng., L.R.C.P. Lond., who was well known during the last ten years to travellers and invalids wintering in Egypt where he practised first on Messrs. Cook's Nile steamers and later at Luxor, in which place in addition to private practice he had charge of the Luxor hospital for natives. No more suitable memorial could have been chosen, as Mr. Longmore took the keenest interest in the question of hospital accommodation for sick natives. His personality was so charming that he made hosts of friends and the subscription list has already been liberally responded to, but the committee require to raise £500. The honorary secretary of the fund in this country is Dr. Barry Blacker, 15, West Eaton-place, to whom subscriptions should be sent.

IN the December number of the *Middlesex Hospital Journal* is a life-like reproduction from a portrait of Dr. Sidney Coupland by the mezzotinto-like process of the Swan Electric Engraving Company. As most of our readers know, Dr. Coupland has had to sever his connexion with the Middlesex Hospital in consequence of his appointment to the post of a Commissioner in Lunacy. It is fitting that the hospital which he has so long and honourably served should issue this portrait as a frontispiece to its *Journal* and as an embellishment to an appreciatory note which concludes: "We wish him a long and very happy career in his new field and feel sure that he will never forget nor lose interest in his many Middlesex friends, who certainly will never forget nor lose interest in their beloved and honoured teacher and colleague."

THE Council of the Royal Institute of Public Health have awarded the Harben Gold Medal for 1899 to Lord Lister, P.R.S., in recognition of his eminent services to preventive medicine; and they have appointed Professor William R. Smith, M.D. Aberd., D.Sc., F.R.S. Edin., as Harben Lecturer for the year 1899, who has chosen as the subject for his lectures "Diphtheria." We hope Professor Smith, who is medical officer to the London School Board, will explain his position as an unbeliever in the influence of the schools in the dissemination of diphtheria.

SIR GEORGE BIRDWOOD has retired from the India Office after a service period of more than forty years. He is best known for his extensive knowledge of the arts and crafts of India and for his organisation of various exhibitions, and we are glad to say that although he has retired the country will have the benefit of his services with regard to the forthcoming exhibition at Paris to be held next year. Sir George Birdwood is an M.D. of Edinburgh and has held important medical and scientific professorships at the Grant Medical College, Bombay.

ON the occasion of the jubilee of the St. Petersburg Academy of Medicine the following British medical men have been appointed honorary members of the Academy: Sir William MacCormac, Sir William Turner, Sir William Stokes, Dr. Thomson, Dr. Macewen, and Dr. Lauder Brunton. Lord Rayleigh received the same honour.

MR. THOMAS TOWNSEND BUCKNILL, Q.C., who has been appointed a Judge of the High Court in the room of Sir Henry Hawkins resigned, is the second son of the late Sir J. C. Bucknill, M.D. Lond., F.R.S., of East Cliff House, Bournemouth, well known as a psychologist and as a pioneer of the volunteer movement.

SIR SQUIRE BANCROFT will tell the story of Charles Dickens's "Christmas Carol" at St. Martin's Town Hall on Thursday afternoon, Jan. 12th, at 3 o'clock, in aid of the Royal London Ophthalmic Hospital. Tickets can be obtained from the Secretary, Royal London Ophthalmic Hospital, Moorfields, E.C.

THE Inebriates Act, 1898, came into operation on Jan. 1st, 1899. It is stated that circulars will be issued from the Home Office to explain the objects of the Act. We hope in a future issue to deal at length with this important subject.

THE January number of the *Quiver* contains an article on Great Anniversaries in January by the Rev. A. R. Buckland and among the calendrical reminiscences is a note on the establishment of the Hospital Sunday Fund. The author calls to mind the fact that "From the year 1869 to the year 1872 the late Dr. James Wakley, Editor of THE LANCET, urged the establishment of such a fund; but it was not until Jan. 16th, 1873, that the meeting which gave birth to the movement was held in the Mansion House. Sir Sydney Waterlow was Lord Mayor that year and he became the first treasurer and president of the Fund." The note is accompanied by a capital likeness of the late Dr. James Wakley and also by one of Sir Sydney Waterlow.

SIR JAMES REID, Bart., K.C.B., has been appointed by the Prince of Wales a Physician-in-Ordinary to His Royal Highness, vice Sir William Jenner, Bart., G.C.B., recently deceased.

LADY CURZON of Kedleston is to become the President of the Marchioness of Dufferin's fund for providing medical aid for the women of India.

THE North London Hospital for Consumption and Diseases of the Chest has received a donation of £3000 from "A Lady."

A SPLENDID New Year's gift has been received by the committee of the Bromley (Kent) Cottage Hospital, in the shape of a donation of £4000 for the endowment in perpetuity of the "Jamie Wheeler-Bennett" children's ward of the hospital. The gift is from Mr. J. Wheeler Bennett of Ravensbourne, Keston, Kent, a member of the committee of the hospital, and already one of the most liberal supporters of this and other charities in the neighbourhood. The ward has accommodation for 6 children's cots and with the growing demands on the accommodation of the hospital this provision for the children's ward will be a great relief to the committee who have a large institution of 32 beds in all to maintain, being the largest institution of its kind in the kingdom.

FATAL ACCIDENT.—Mrs. Bowen-Jones, the wife of Mr. L. M. Bowen-Jones, the medical officer of health of the Carmarthen Combined Rural Districts, was thrown out of a carriage on Christmas Day and fractured the base of her skull. She died the same evening. At the inquest a verdict was returned in accordance with the evidence and a vote of sympathy with Mr. Bowen-Jones was passed.

THE LANCET
Analytical Commission
ON
SOME LEADLESS GLAZES

LEAD poisoning in the potteries proceeds apace, and must do so until, as we have remarked before in these columns,[1] the Home Office takes one of two courses—either prohibits the use of raw lead, or by suitable regulations makes the introduction of harmless glazes a paying or practicable affair for the manufacturer How urgently prompt and effective legislative action is needed is evident when we consider that under the new Act of 1895 the returns for the year 1896 showed 387 cases of lead poisoning from the potteries, and further statistics show a decided increase upon this number English pottery work and English pottery products stand first in the world It is a terrible stigma, however, upon this position that in some branches at least this excellence is attained at the expense of so much human suffering

The seat of the mischief, as everyone knows, is lead, and the question to be decided is whether raw lead can be made harmless, or dispensed with altogether To make raw lead harmless it has been suggested to fuse it first with borax, silica, &c —a process technically termed "fritting '—but clearly this preliminary precaution involves the handling of raw lead in the preparatory stage The risk, however, of lead poisoning would be thus considerably lessened where it now most occurs—that is, in the cases of those whose business it is to grind the "frit into powder and to dip the ware in the glaze subsequently prepared The lead in a "frit ' is much less soluble in the gastric juice than is raw lead and the evil effects of absorption of lead during both the grinding and dipping processes would be largely avoided by the adoption of "fritted lead

In an article published in THE LANCET of May 14th, 1898, we had occasion to sum up the opinions of manufacturers as to the practicability of substituting "fritted" lead for raw lead and the balance of opinion seemed to be decidedly in favour of the former Amongst these opinions the following are worthy of observation "'Fritted' lead is as consistent with practical pottery as using the lead as in the raw state, it is an easier flux than raw lead and can be used universally without injury to the trade, it does better for colours and increases the brilliancy of the ware, and, finally (according to the evidence of an employé in one of the largest pottery firms), not a single case of lead poisoning had been known where all the lead was 'fritted'"

We next turn to the possibility of doing away with lead altogether Obviously, could this be done without interfering with the peculiar and delicate requirements of the art of glazing we might confidently hope for a speedy and satisfactory solution of a very difficult question An enormous number of laborious experiments have been made on this promising side of the subject, with the result we may hope that the introduction and adoption of practicable leadless glazes will become before long an accomplished fact But obviously nothing short of the evidence of experience can be expected to satisfy the industry on all points As a small, though we think encouraging and instructive, contribution to the question we now offer the results of some experiments which we ourselves have made with certain leadless glazes in THE LANCET Laboratory during the last month We cannot, of course lay claim to the possession of practical knowledge or judgment in this matter Our interest in the question is necessarily a limited one but it is a vital interest, the points at issue affecting the well being of those engaged in a beautiful but at present dangerous art

Our attention was recently drawn to the important results of a great number of arduous experiments directed to the practicability of producing leadless glazes which were undertaken by one who has spent much of his time in the potteries and who has an extensive practical acquaintance with the industry These results have been published by the author,[2] Mr William J Furnival, the failures as well as successes being wisely recorded Some of the successes are illustrated in specimens placed on view, by permission of the Science and Art Department in the Geological Museum in Jermyn-street By the courtesy of Mr Furnival we have obtained some specimens of the glaze and of the wares finished by its means They consisted of various types, such as saucers, cheese plates, dessert plates, plaques &c, all of which we have examined, tested, and submitted to experiment

No 1 was a leadless glaze marked No 2855 and described as having been used in the dipping of all the samples of ware marked 2855 Examined for lead this glaze gave absolutely negative results Borax was an important constituent When tried on "biscuit" in the oxyhydrogen flame a clear uniform glaze resulted

The second specimen was a saucer one half of which was glazed with lead glaze and the other half with leadless glaze This appeared to us to be a perfectly successful demonstration of the practicability of using leadless glaze In appearance the leadless glaze was in every way as good as the lead glaze Careful chemical tests showed the presence of lead in the one case and the absence of lead in the other

The specimen taken as a third example was a dessert-plate with coloured pattern and gold border. The glaze was excellent and was free from lead

These examples will suffice but we may add that we have examined and tested in all fourteen pieces[3] with satisfactory results The lead was tested for in two ways First, on a portion of the plate a mixture of carbonate of soda and potash was fused before the flame of a powerful blowpipe The melted mass after cooling was washed off in hot dilute hydrochloric acid and sulphuretted hydrogen was passed through the solution There was never any indication of lead in the glazes marked "leadless" As a check on this test the plate was afterwards sprinkled with powdered fluorspar and moistened with strong sulphuric acid and gently warmed The glaze was thus attacked by the hydrofluoric acid generated and the lead, if present, would be liberated from the flux The plate was next flooded with water and sulphuretted hydrogen was passed through the liquid This test answered very well with ordinary lead glazed ware but in no case gave any positive response with the leadless glazed ware so described and placed at our disposal by Mr Furnival

We consider that these results are of the utmost importance for they indicate the probability of satisfactorily substituting absolutely leadless glaze for the old lead veneer without detriment to the beauty and finished appearance of the product It seems to us, therefore, that the ground should be perfectly clear for action by the Home Office Either leadless glazes are practicable or they are impracticable It is for a committee of experts to decide one way or the other with the evidence of practical trial before them. There is no proprietary right whatever connected with the use of these glazes Their formulæ are published and fair practical trial and criticism are invited We understand that already some large pottery manufacturers and others with a considerable experience of the industry have tried these leadless glazes on a practical scale with excellent results

It may be hoped, then, that the day is not far distant when the Government will be in a position to demand the abolition of raw lead in glazing and to compel the adoption of safe "frits' or, better still, leadless glazes, without inflicting any hardship on the potter or causing any hindrance to the pursuit of his art The alternative is to bring lead poisoning under the Workmen's Compensation Act

THE LANCET Laboratory

THE METROPOLITAN WATER-SUPPLY: THE PROPOSED BATTERSEA INTER-COMMUNICATION SCHEME

IN October, 1897, the engineers of the metropolitan water companies proposed a scheme to make interchangeable connexions between the mains of the several companies This scheme was submitted to Lord Llandaff's Commission At a meeting held on Oct 24th of the present year by the engineers of the metropolitan water companies a second report was made and a new scheme was drawn up This is called Scheme No. 2. Sir Henry Knight, chairman to the Southwark and Vauxhall Company, in giving his evidence proposed a scheme differing somewhat from both the schemes just mentioned. This is called Scheme No. 3. The second scheme is the one which is here described. A diagram is given showing the proposed trunk mains. The scheme will be best understood by a study of this map in connexion with the evidence given by Mr. Collins of the outline of the scheme. Mr. Collins's evidence, given at the thirty-fifth sitting of the Royal Commissioners, was as follows :—

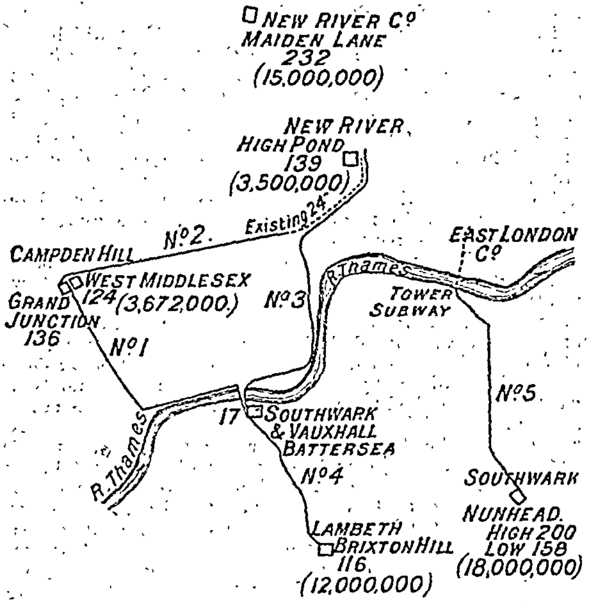
---

[1] THE LANCET Nov 19th 1898

[2] This book ("Researches on Leadless Glazes") was reviewed in THE LANCET of Nov 19th 1898

[3] We shall be pleased to show these specimens as tested in THE LANCET Laboratory to those of our readers who are interested in the subject and who for that purpose will kindly write to us requesting an appointment

PLAN SHOWING PROPOSED TRUNK MAINS TO BE MADE IN THE "BATTERSEA SCHEME (NO. 2)."



Nos. 1, 2, 3, and 4 are the proposed *new* trunk mains for the supply of water from the Southwark and Vauxhall Company's Battersea station. The figures in brackets give the capacities of the reservoirs in gallons. The figures immediately under the names of the reservoirs give the height in feet above Ordnance datum at which the reservoirs are situated.

"The idea is to take the Battersea works as a centre. These works are capable of filtering 15,000,000 gallons a day with pumping power for 25,000,000 gallons a day. That being the case it would be possible by the running of certain mains to make a distribution between all the companies which would be available not from any one company to any other company, but from all the companies to any one company. That would necessitate the laying of certain mains. If you will refer to the plan attached to the scheme you will see there is a main put down as No. 1. That is the line between Battersea and Campden-hill. That is what we call No. 1 connexion, and that would enable water in the first instance to be taken from Battersea to Campden-hill direct. That main would be the means of assisting the Grand Junction Company to a quantity equal to 10,000,000 gallons per day from Battersea, and would also be available for passing water back from Campden-hill to Battersea in case the assistance is required for other companies. No. 2 connexion upon the plan consists of a main between the Campden-hill reservoir and the New River head. That main is already partially laid. No. 2 connexion, which would enable the Grand Junction Company to pass water from their Campden-hill reservoirs into the New River, would be for the assistance of the New River Company; and at the same time it could receive assistance from Battersea into Campden-hill, so it would be a circulation round from one company to another. Then, again, for the assistance of the New River Company it is suggested that main No. 3 should be laid. That would enable the Southwark and Vauxhall Company to pass 10,000,000 gallons a day through to the New River Company. No. 4 main would enable the Battersea centre to deliver water to Brixton; and No. 5 main is the main which is already partially made under the river and would enable the Southwark and Vauxhall Company, without interference with the present supply, to give a suitable quantity to the East London Company. With these means of connexion as set forth in what we call No. 2 scheme a complete circuit of connexions is formed—that is, a system by which almost 20,000,000 gallons a day can be provided for any one company in case that company is in trouble in case of an emergency. We have set forth in this No. 2 report a list of the mains and connexions which we say might be made. We do not bind *ourselves that this is the only scheme that might be adopted*; it is subject to alteration if necessity requires. After those connexions we give you the proposed quantity of water that could be delivered to any one company from the different sources. We take first of all the Chelsea as the receiving company, and we say that through the main No. 1 we could by making a connexion pass water to the Chelsea Company either from Battersea or from Campden-hill. Assistance could be rendered to this company, we say, through connexions with main No. 1."

The details of the scheme are as follows. The trunk mains which will have to be made are :—

No. 1. A 30 in. main from Battersea Works to Campden-hill, about 6380 yards in length.

No. 2. A 24 in. main from Campden-hill to Poland-street, about 5100 yards.

No. 3. A 30 in. main from Battersea Works to the "Angel," Islington, in connexion with the New River Company's Crouch-hill system, about 8800 yards (providing for duplication across the Thames).

No. 4. A 30 in. main from Battersea Works to Brixton-hill, about 3960 yards.

No. 5. A 30 in. main from Nunhead reservoir to the Tower subway, about 5700 yards.

No. 6. A 21 in. main from Hammersmith to Campden-hill to enable the West Middlesex Company to deliver 3,000,000 gallons per day into Campden-hill reservoir.

No. 7. A 24 in. main, about four miles in length, to enable the Grand Junction Company to deliver 3,000,000 gallons per day extra into Campden-hill reservoir.

The following connexions would also have to be made :—

1. A connexion between the West Middlesex Company's main in the vicinity of Campden-hill and the Grand Junction Company's Campden-hill reservoir.
2. A connexion at Raynes Park between the 42 in. main of the Southwark and Vauxhall Company and the two 30 in. mains of the Lambeth Company.
3. A connexion at Leigham Court-road, Streatham, between the 21 in. main of the Lambeth Company and the 42 in. main of the Southwark Company.
4. A connexion at Kennington-gate between the 20 in. and 24 in. mains of the Lambeth Company and the 30 in. and 24 in. mains of the Southwark Company.
5. A connexion at Manor-park, Streatham, between the Streatham works of the Southwark Company and the 12 in. main of the Lambeth Company.
6. A connexion between the 12 in. main of the Lambeth Company in Park-road, Forest-hill, and the 12 in. main of the Kent Company in High-street, Lewisham.
7. A connexion between the 12 in. main of the Lambeth Company at Beckenham and the 12 in. main of the Kent Company at Shortlands.
8. A connexion at Peckham between the 16 in. main of the Kent Company and the 20 in. main of the Southwark Company.
9. A connexion at Upper Richmond-road, Putney, between the 24 in. main of the Chelsea Company and the 30 in. and 36 in. mains of the Southwark Company.
10. A connexion at London-road, Kingston, between the 42 in. main of the Southwark Company and the 30 in. and 24 in. mains of the Chelsea Company.
11. A connexion at Surbiton between the 30 in. main of the Lambeth Company and the 30 in. main of the Chelsea Company.
12. A connexion at Kingston-hill between the two 12 in. mains of the Lambeth Company and the 30 in. and 15 in. mains of the Chelsea Company.

The following connexions which already exist would also be utilised :—

1. A connexion by which the Grand Junction Company can pump directly into the mains of the East London Company and *vice versâ*.
2. An arrangement by which water can be delivered by the East London Company to the New River Company from their 30 in. main in Seven Sisters-road into the New River.

The proposed mains of intercommunication would approximately be as follows :—

RECEIVING COMPANY—THE CHELSEA.

	Gallons per day.
Assistance could be rendered to this company through connexions with Trunk Main No. 1 crossing 24 in. mains of the Chelsea Company, by which water could be delivered from the Battersea centre to the extent of...	10,000,000

Failing this, 10,000,000 gallons could be delivered from Campden-hill by means of these connexions, the Grand Junction Company contributing 3,000,000 gallons, the West Middlesex Company 3,000,000, and the New River Company 4,000,000.

Further assistance could be rendered to the Chelsea

Company by connexions Nos. 9, 10, and 11, which provide for an interchange of water between the Southwark and Chelsea and Lambeth and Chelsea Companies.

RECEIVING COMPANY—EAST LONDON.

Assistance could be rendered to this company as follows:—

	Gallons per day.
From the New River Company at Lee intake ...	6,000,000
From the Grand Junction Company, 3,000,000 gallons, and from the West Middlesex Company, 3,000,000 gallons; total delivered at New River Head to be passed on to East London Company by Lee intake	6,000,000
From the Southwark Company per Tower Subway Trunk Main No. 5 supported from Battersea centre	8,000,000
Total	20,000,000

Further assistance could be rendered to the East London Company by the existing connexion with the Kent Company at Blackwall to the extent of 500,000 gallons per day.

The Chelsea and Lambeth Companies, in the event of failure of the foregoing proposals, by means of connexions Nos. 9, 10, 2, 3, 4, and 5 could assist the Southwark Company, which in turn could assist the East London Company with water so provided.

RECEIVING COMPANY—GRAND JUNCTION.

Assistance could be rendered to this company as follows:—

	Gallons per day.
From New River Company per Trunk Main No. 2	6,000,000
From West Middlesex Company	3,000,000
From Battersea centre per Trunk Main No. 1	10,000,000
Total	19,000,000

RECEIVING COMPANY—KENT.

	Gallons per day.
Assistance could be rendered by means of connexions Nos. 6 and 7 from the Lambeth and No. 10 from the Southwark Company to the extent of, say	4,000,000

This in turn could be supplemented from Battersea centre.

RECEIVING COMPANY—LAMBETH.

	Gallons per day
Assistance could be rendered from Battersea centre per Trunk Main No. 4 to the extent of	10,000,000
From the Grand Junction Company per Trunk Main No. 1 from Campden-hill direct to *Brixton*	3,000,000
From West Middlesex Company per Trunk Mains Nos. 1 and 4	3,000,000
From New River Company *via* Campden-hill	4,000,000
Total	20,000,000

This could be supplemented from the Chelsea Company by connexions Nos. 11 and 12 and from the Kent Company by Nos 6 and 7.

RECEIVING COMPANY—NEW RIVER

	Gallons per day.
Assistance could be rendered to this company from Grand Junction Company per Trunk Main No. 2	3,000,000
From West Middlesex Company per Trunk Main No. 2	3,000,000
From Battersea centre per Trunk Main No. 3	10,000,000
Further assistance could be rendered by the East London Company through the existing connexion with the New River at Seven Sisters-road to the extent of	4,000,000
Total	20,000,000

RECEIVING COMPANY—SOUTHWARK AND VAUXHALL.

Assistance could be rendered to this company as follows:—

	Gallons per day.
From the Battersea centre	10,000,000
From the New River, West Middlesex, and Grand Junction Companies, per Campden-hill	10,000,000
Total	20,000,000

Assistance could also be given by the Lambeth and Chelsea Companies by means of connexions Nos. 2, 3, 4, 5, 9, and 10.

RECEIVING COMPANY—WEST MIDDLESEX.

Assistance could be rendered to this company as follows:—

	Gallons per day.
From New River Company, per Trunk Main No. 2	6,000,000
From Grand Junction Company	3,000,000
From Battersea centre, per Campden-hill	10,000,000
Total	19,000,000

Further assistance could be given from the New River Company by the existing connexions at Tottenham Court-road and at Euston-road.

Upon the supposition that the Battersea works can be made available, the terms upon which they might be utilised would have to be arranged between the eight confederated companies.

The provision of a 36-in main from Hampton to Battersea would make Battersea a permanent centre This main could not be laid before next summer, but the existing one would be sufficient until its completion.

THE MIDWIVES BILL.

THE Memorandum of the new Midwives Bill, which it is intended to introduce into Parliament next Session, runs as follows:—

The chief object of this Bill is to carry into effect the recommendations of the Select Committee of the House of Commons relating to the training and practice of midwives by promoting the training of women as midwives and by providing for the regulation of their practice.[1] This Bill provides that henceforth no woman shall call herself, or habitually practise for gain as, a midwife unless she has obtained a licence, and that, in order to be licensed, she must *inter alia* produce evidence either (1) of having undergone a proper training and subsequent examination, or (2) of having (at the time of the passing of the Bill) been in *bonâ fide* practice as a midwife. The Bill does not render it illegal for any person to render assistance to a lying-in woman in an emergency. A Central Midwives Board is constituted under this Bill whose chief duties will be (1) to organise examinations of a uniform standard; (2) to regulate, supervise, and restrict within due limits the practice of midwives; and (3) to investigate charges of malpractice, negligence, or ignorance against midwives.

The Bill is drafted on the lines of that introduced last year, but the following alterations have been made in view of the requirements of the *General Medical Council*[2]:—(1) Licensing is substituted for registration; (2) the habitual practice of midwifery for gain by women not licensed under this Bill is rendered illegal; and (3) the area within which a midwife may practise is, in order to facilitate supervision, limited to that of the local supervising authority from whom she has obtained a certificate authorising her to practise.

---

[1] See Reports of Select Committee on Midwives Registration together with the Proceedings of the Committee, Minutes of Evidence, Appendix, and Index ordered by the House of Commons to be printed June 17th, 1892, and August 8th, 1893

[2] See report by the committee appointed by the General Medical Council on May 25th, 1898, to confer with delegates from the Midwives Bill Committee, together with an appendix containing a report of the proceedings at the Conference (adopted by the General Medical Council, Nov. 29th, 1898).

Draft Copy of the Midwives Bill.

A Bill to Promote the Better Training of Women as Midwives and to Regulate their Practice.

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. This Act may for all purposes be cited as the Midwives Act, 1899.

2. In this Act, the term "midwife" means a woman who undertakes for gain to attend women in child-birth. "Midwives Roll" means a roll of midwives kept in pursuance of this Act. "Central Midwives Board" means the Board constituted under this Act for the purpose of carrying out the provisions of this Act.

3.—(1) From and after the first day of January, one thousand nine hundred, no woman shall be entitled to take or use the name or title of midwife (either alone or in combination with any other word or words) or any name, title, addition, or description implying that she is licensed under this Act or is qualified to act as a midwife unless she be licensed under this Act. (2) Any woman who, after the first day of January one thousand nine hundred, not being licensed under this Act, shall take or use the name of midwife or any other such name, title, addition, or description as aforesaid, or shall habitually and for gain attend women in child-birth shall be liable on summary conviction to a fine not exceeding five pounds. (3) No woman shall be licensed under this Act until she has complied with the rules and regulations to be laid down in pursuance of the terms of this Act. (4) The licence under this Act shall not confer upon any woman any right or title to be registered under the Medical Acts or to assume any name, title, or designation implying that she is by law recognised as a medical practitioner or that she is qualified to grant any medical certificate.

4. Any woman who, within two years of the passing of this Act, claims to be licensed under this Act shall be so licensed provided she holds a certificate in midwifery from the Royal College of Physicians of Ireland or from the Obstetrical Society of London or such other certificate as may be approved by the Central Midwives Board, or produces evidence, satisfactory to the Board, of character, and that at the passing of this Act she has been in bonâ-fide practice as a midwife.

5. On the passing of this Act the President of the General Medical Council shall take steps to secure the election of a Central Midwives Board which shall consist of:—(1) Four registered medical practitioners, one to be elected by the Royal College of Physicians of London, one by the Royal College of Surgeons of England, one by the Society of Apothecaries, and one by the Incorporated Midwives Institute; and (2) two persons to be appointed for terms of three years by the Lord President of the Council. After two years from the passing of this Act the elected members shall retire but shall be eligible for re-election annually. Any vacancy occurring by resignation or death shall be filled up in the case of an elected member by the body which elected him, and in the case of an appointed member by the Lord President of the Privy Council. (3) The duties of the Board shall be as follows:—

I.—*To frame rules, for approval by* the General Medical Council, (*a*) regulating the issue of licences and the conditions of admission to the roll; (*b*) regulating the conduct of qualifying examinations; (*c*) regulating the admission to the roll of women already in practice as midwives at the passing of this Act; (*d*) regulating, supervising, and restricting within due limits the practice of midwives.

II.—(*a*) To appoint examiners; (*b*) to decide upon the places where and the times when examinations shall be held; (*c*) to publish annually a roll of midwives who have been duly licensed under the Act; (*d*) to decide upon the conditions under which midwives may be suspended from practice; (*e*) to decide upon the removal from the roll of the name of any midwife for disobeying the rules and regulations from time to time laid down under this Act by the Central Midwives Board, or for other misconduct, and also to decide upon the restoration to the roll of the name of any midwife so removed; (*f*) to issue licences.

III.—And generally to do any other act or duty which may be necessary for the due and proper carrying out of the provisions of this Act.

6. There shall be payable by every woman presenting herself for examination or licence such fees as the Central Midwives Board may, with the approval of the General Medical Council, from time to time determine. All fees paid by existing midwives and by candidates for examination shall be paid to the Central Midwives Board. The said Board shall devote such fees to the payment of expenses connected with the examination and licence and to the general expenses of the Board. Should these fees not equal the expenditure of the Board the deficiency shall be supplied from the respective local administrative county funds in proportion to the number of licensed midwives in the said county.

7. There shall be a Midwives Roll containing: (1) the names of those midwives practising at the date of the passing of the Act who have been licensed to practise under the Act; (2) the names of those not already in practice as midwives at the passing of the Act but who have been licensed to practise under the Act. The entry on the roll shall in every case indicate the qualifications in virtue of which the licence was granted.

8. The Central Midwives Board shall appoint a secretary who shall be charged with the custody of the roll. A copy of the midwives roll for the time being shall be evidence in all courts that the women therein specified are licensed according to the provisions of this Act; and the absence of the name of any woman from such copy shall be evidence, until the contrary be made to appear, that such woman is not licensed according to the provisions of this Act. Provided always that in the case of any woman whose name does not appear in such copy a certificate under the hand of the secretary of the entry of the name of such woman on the roll shall be evidence that such woman is licensed under the provisions of this Act.

9. Every administrative county council throughout England and Wales shall, on the passing of this Act, appoint its medical officer of health or other registered medical practitioner or practitioners, as the local supervising authority over midwives within the area of the said county. It shall be the duty of the local supervising authority: (1) To exercise general supervision over all midwives practising within the prescribed area in accordance with the rules to be laid down under the provisions of this Act. (2) To investigate charges of malpractice, negligence, or misconduct on the part of any midwife practising within his district, and if he consider that a *primâ facie* case is established to report the same to the Central Midwives Board. (3) To suspend any midwife from practice, in accordance with the rules to be laid down by the Central Midwives Board, if he considers such suspension necessary to prevent the spread of infection. (4) To report at once to the said Board the name of any midwife practising in his district convicted of a misdemeanour or felony. (5) During the month of January of each year to supply the secretary of the Central Midwives Board with the names and addresses of all midwives practising in his district and to keep a current copy of the midwives roll accessible at all reasonable times for public inspection. (6) To report at once to the Central Midwives Board the death of any midwife or any change in the name or address of any midwife in his district so that the necessary alteration may be made in the roll.

10. A woman who holds herself out as a practising midwife in any administrative county shall obtain from the local supervising authority a certificate enabling her to practise therein, which certificate shall be granted on proof by the woman that her name is on the midwives roll. The certificate shall remain in force till the thirty-first of December following, and shall be revocable at any time by the local supervising authority in case the holder be proved, to the satisfaction of the Central Midwives Board, to have infringed any of the *regulations* framed under this Act. The certificate shall be renewed annually in the month of January. It shall be issued free of charge and shall only be available in the county for which it is issued.

11. (*a*) Any woman who procures or attempts to procure a licence by making or producing, or causing to be made or produced, any false or fraudulent declaration, certificate, or representation, either in writing or otherwise, and any person assisting her therein, shall be deemed guilty of a misdemeanour, and shall on conviction thereof be liable to a fine not exceeding £5, or to be imprisoned, with or without hard labour, for any term not exceeding two months. (*b*) Any woman who, after the first day of January, one thousand nine hundred, shall hold herself out as a practising midwife or shall practise in any administrative county without having previously obtained from the local supervising authority a certificate *enabling her to practise therein* shall be deemed guilty of a misdemeanour and shall, on conviction thereof, be liable to a fine not exceeding two pounds or to be imprisoned, with or without hard labour, for any term not exceeding one month. (*c*) But a midwife shall not be guilty of a misdemeanour under this section by attending, on an emergency, a woman in childbirth in a county other than that for which she holds a certificate; provided she has within a reasonable time given notice of having so acted to the local supervising authority of that county.

12. Any person appointed to keep the roll of midwives, wilfully making or causing to be made any falsification in any matter relating to the roll of midwives shall be deemed guilty of a misdemeanour and shall be liable to a fine not exceeding ten pounds, or to be imprisoned with or without hard labour for any term not exceeding three months.

13. Any offences under this Act punishable on summary conviction may be prosecuted, and any fine under this Act recoverable on summary conviction may be recovered, in manner provided by the Summary Jurisdiction Acts. The expenses of any prosecution shall be defrayed out of the funds of the county in which the prosecution takes place.

14. (1) An appeal shall be allowed to the Privy Council should any disagreement arise between the General Medical Council and the Midwives Board respecting the carrying out of the provisions of the Act or of any of them; (2) where any woman deems herself aggrieved by any order, conviction, judgment, or *determination* of or by any matter or thing done under this Act by any court of summary *jurisdiction*, such woman may appeal therefrom to the court of quarter sessions.

15. Nothing in this Act respecting midwives shall apply to legally qualified medical practitioners.

16. This Act shall not extend to Scotland or Ireland.

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

THE Honorary Secretaries of this Fund have kindly forwarded to us the following report of the Prince of Wales's Hospital Fund for the year:—

With the approval of His Royal Highness (the President) the operations of the Fund have this year been limited to those hospitals lying within a radius of seven miles from Charing-cross which applied for a grant within the stated time in answer to the advertisement inserted in the metropolitan journals. In the preliminary consideration of these applications the Visiting Committee received great help from the Central Hospital Council for London. Of those hospitals which applied and whose claims were considered all but 12 received grants. Of these 12 some were deemed by their existing income and by the grants already received from the Sunday and Saturday Funds to be this year adequately provided for. Others, though excellent institutions, did not appear to be hospitals in the strict sense; a few more were, by reason of their management, ruled to be undeserving of support. The 100 dozen pints of champagne presented by Messrs. Charles Heidsick have been stored by Messrs. Thomas Trapp and Sons, who have undertaken to deliver them to the various hospitals free of cost. This wine is divided among the hospitals receiving grants approximately in proportion to the number of beds occupied, exclusive of pay beds. The details of the grants for this year are appended below:—

Grants Recommended by the Distribution Committee.

Name of Hospital.	Grant.	
	Annual.	Donation.
	£	£
[1] London Hospital	5000	—
[1] Guy's Hospital	5000	—
[1] St. Thomas's Hospital	1500	—
[1] Middlesex Hospital	1000	—
[1] St. Mary's Hospital	1000	—
[2] King's College Hospital	1000	475
[3] Westminster Hospital	750	—
[3] University College Hospital	1400	—
[3] Charing-cross Hospital	1000	—
[3] Royal Free Hospital	750	—
[3] Seamen's Hospital	500	—
[4] Hospital for Consumption, Brompton	—	500
[5] Hospital for Sick Children, Great Ormond-street, W.C.	500	—
[5] City of London Hospital for Diseases of the Chest, Victoria-park, E.	1000	—
[5] National Hospital for the Paralysed and Epileptic	750	—
Metropolitan Hospital	—	500
[6] Great Northern Central Hospital	750	—
German Hospital	—	150
[7] London Temperance Hospital	—	500
[8] West London Hospital	—	500
French Hospital	—	100
West Ham Hospital	—	250
North West London Hospital	—	300
Mildmay Mission Hospital	—	250
[9] Bolingbroke Hospital	—	250
Miller Hospital	—	200
Memorial Cottage Hospital	—	50
[10] Establishment for Gentlewomen, Harley-street	—	75
St. Saviour's Hospital, Osnaburgh-street	—	50
Royal Hospital for Diseases of the Chest, City-road	—	100
[11] North London Hospital for Consumption	1000	—
[12] East London Hospital for Children	—	250
Alexandra Hospital for Children	—	500
[13] North Eastern Hospital for Children	—	250
Paddington-green Hospital for Children	—	150
Royal Hospital for Children and Women	—	100
[14] Samaritan Free Hospital	—	500
[15] Grosvenor Hospital for Women and Children	—	100
Hospital for Women, Soho-square	—	350
Chelsea Hospital for Women	—	300
Queen Charlotte's Hospital	—	300
British Lying-in Hospital	—	50
[16] Royal London Ophthalmic Hospital	—	450
[17] London Lock Hospital (Female)	—	500
St. Peter's Hospital for Stone	—	50
London Homœopathic Hospital	—	200
Total	23,200	8,300

COMMITTEE'S RECOMMENDATIONS.

[1] The Committee recommend that the grant be made on the same conditions as last year's.

[2] The Committee recommend that the annual grant of £1000 be continued and that a special grant of £475 be made towards reflooring the wards.

[3] The Committee recommend that the annual grant be continued on the same conditions as last year's.

[4] The Committee recommend that this grant be made towards the cost of the proposed country branch and convalescent home on condition that the balance of the estimated cost is provided and the work put in hand without any avoidable delay.

[5] The Committee recommend that this grant be made in order to provide for the reopening of 15 of the 60 beds now closed.

[6] The Committee recommend that this grant be made on condition that 15 of the 25 beds now closed are opened.

[7] The Committee recommend that this grant be made on condition that the further sum necessary to open the closed ward (12 beds) is raised and the ward opened.

[8] The Committee recommend that this grant be made in the expectation that the overcrowding in the old wards will be abolished and that the suggestions of the Visitors be communicated to the hospital authorities.

[9] The Committee recommend that this grant be made towards the cost of a new accident ward on condition that the balance of the estimated cost is provided and the work put in hand without any avoidable delay.

[10] The Committee recommend that this grant be made only on the understanding that a properly constituted committee is elected forthwith.

[11] The Committee recommend that this grant be made on condition that 15 out of the 20 beds now closed are opened.

[12] The Committee recommend that this grant be made towards a new operating theatre.

[13] The Committee recommend that this grant be made in anticipation of improvements being made in the directions indicated by the Visitors.

[14] The Committee recommend that attention be called, in making the grant, to the overcrowded state of the out-patient department, and that the suggestion be made that it might temporarily be remedied by the children as out-patients being referred to children's hospitals.

[15] The Committee recommend that attention be called in making this grant to the high cost per in-patient per week.

[16] The Committee recommend that attention be called in making this grant to the substance of the Visitors' recommendations.

[17] The Committee recommend that this grant be made on the understanding that the amount necessary for the reconstruction of the drainage of the hospital be provided and the work put in hand without any avoidable delay; and that the overcrowding in wards Nos. 1, 5, 7, 8, 9, and 10 reported by the Visitors be abolished.

Grants Recommended by Convalescent Hospitals Committee.

Metropolitan Convalescent Institution, 32, Sackville-street, Piccadilly, W.	£200
Morley House Seaside Convalescent Home, St. Margaret's Bay, Dover	200
Mary Wardell Convalescent Home, Stanmore, Middlesex	100
Royal Sea Bathing Hospital, Margate	100
Charing-cross Hospital, Convalescent Home at Limpsfield	50
Chelsea Hospital for Women, Convalescent Home at St. Leonards-on-Sea	50
East London Hospital for Children, Convalescent Home being erected at Bognor	50
King's College Hospital, Convalescent Hospital, Hemel Hempstead	50
Middlesex Hospital, Convalescent Home at Clacton-on-Sea	50
National Hospital for Paralysed and Epileptic, Convalescent Home at East Finchley	50
Queen Charlotte's Hospital, Convalescent Home at Kilburn	50
Metropolitan Hospital, Convalescent Home at Cranbrook	25
Paddington Green Children's Hospital, Convalescent Home at Harrow	25
	£1,000

Summary.

Grants to Hospitals	£31,500
Grants to Convalescent Hospitals	1,000
Grand Total	£32,500

Thus the £32,500 distributed this year is shared by 59 hospitals and convalescent homes. The result is that in addition to supplying other specified needs 57 more closed beds will be reopened, making with 185 reopened last year in all 242 closed beds not only reopened but maintained through the Fund.

THE BATTLE OF THE CLUBS.

MEDICAL AID ASSOCIATIONS AND PROFESSIONAL SWEATING.

FOR about six months clubdom in Wigan has been agitated to some extent owing to the action of the Medical Guild. Before the Workmen's Compensation Act came into operation the members of the guild unanimously adopted the following rules:—

1. That no member of the guild shall attend trade accidents in connexion with friendly society sick clubs. By "trade accident" is meant "any injury sustained by a workman whilst following his usual occupation."
2. That the minimum fee for attendance on any sick and accident clubs shall be 5s. per head per annum—i.e., 2s. 6d. for sickness and 2s. 6d. for accident.
3. That the fees charged for examination and report in cases proceeding to arbitration under the Workmen's Compensation Act, 1897, be the same as allowed by the Treasury.[1]
4. That the minimum fee for a preliminary report upon any accident under the Workmen's Compensation Act, 1897, be 1 guinea.

These rates are surely low enough, yet we find that some of the friendly societies took exception to this, although they generally admitted that the miner had made provision for his accidents in the Lancashire and Cheshire Miners' Permanent Relief Society. Several meetings have been held and a deputation met the council of the Medical Guild asking that the circular containing the rules above mentioned should be withdrawn, but the Medical Guild being conscious of the fairness of the terms mentioned in the rules resolved unanimously to abide by their decision. Now they are threatened with the establishment of a medical aid association in the town and the societies interested have issued a report in which they conclude "that should a medical association be instituted it will confer a lasting benefit on the friendly societies in the district." Added to this are extracts from balance-sheets of similar societies and these are interesting and certainly demand the careful consideration of the profession if not of the General Medical Council itself. It is deplorable after the cost and the time spent in a medical education that men can be found to take such appointments. The balance-sheet of the Warrington Association for the year 1897 showed twenty-five societies with a total membership of 3265. The income was from all sources £547 15*s.* 11*d.* The expenditure for the same period was £551 13*s.* 7½*d.*, thus showing a deficiency of £3 17*s.* 8½*d.* This was accounted for by extraordinary expenditure, such as paving the street, £24 9*s.*; replacing surgery chairs, £5 7*s.* 3*d.* The previous year there was a profit of £23 7*s.* 4*d.* Now for the interesting portion. The medical officer who has seen ten years' service received with allowances £231 6*s.* and for this he paid 4694 visits and gave 15,988 prescriptions, the average number per day being 44, including Sunday. Now, the money value works out at 11*s.* 8$\frac{1}{11}$*d.* per day and 3$\frac{5}{11}$*d.* per prescription, with the visits thrown in. Can this be termed anything else than "sweating"? The Preston Association for the year ending Dec. 21st, 1896, gives a balance on the year's working of £28 10*s.* 10½*d.* The medical salaries were £385 12*s.* 4*d.*; probably this includes the dispenser. During the year 11,878 prescriptions were dispensed, 13,064 attendances were made at the surgery, 5136 visits were paid, and 32 confinements were attended and 18 vaccinations. The Preston Medical Aid Association is worth £1296 14*s.* The Manchester Association employs three surgeons and pays them £459 7*s.* 6*d.*, equal to £153 2*s.* 6*d.* each, and has a balance to the good of £119 10*s.* 9½*d.* on the year's working. Now if a new medical aid association is to be formed on lines similar to these surely the profession will be found to contain men who are honourable enough to uphold its dignity as well as their own and who will refuse to be sweated by a combination of societies which refuses fair terms to their medical officers. The "sixpenny dispensary man" is looked down upon and practically ostracised by his professional neighbours, but what can a medical man who is the servant of a lay committee expect when he is selling his services at a less sum than the man with an independent dispensary?

---

[1] See THE LANCET, April 23rd, 1898, p. 1138.

PUBLIC VACCINATORS OF THE STAINES UNION.

MR. C. DWIGHT MORRIS, the medical officer of health of the Staines Union, recently called a meeting of all the public vaccinators in his union to discuss the provisions of the new Vaccination Act. At this meeting, which all the public vaccinators in the district attended, it was unanimously resolved that they would be prepared to accept the following scale of fees which they trusted their board would agree to:—

Article 3, General Orders.—Sub-section (*a*), 2*s.* 6*d.*; sub-section (*b*), 6*s.*; and sub-section (*c*), 2*s.* 6*d.* That the postage as before be paid by the board—i.e., the various forms be stamped as before. The arrears cases to be subject to special arrangement as there appears to be no definite provision made for these (the Act dealing with cases registered after August 31st, 1898).

The public vaccinators arrived at the above conclusions after mature deliberation on the great difference in the character of the work as performed by them under the old contract and that required to be performed under the new regulations, which is roughly shown in the following scheme. The above scale is only slightly over the minimum as fixed by the Local Government Board; thus, taking into consideration that it is fully expected that a large number of persons will avail themselves of the conscience clause the actual cost will probably be very much less than under the old compulsory Act.

SCHEME SHOWING DIFFERENCE IN CHARACTER OF WORK TO BE DONE UNDER THE OLD ACT AND THE NEW.

The old regulations.—Stations appointments. Appointments four times a year. To vaccinate. Keep register. Forward accounts to vaccination officer. Only three forms required.

The new regulations.—Receive list from vaccination officer every week (Form H). Issue notices to parents (Form I). Visit and offer to vaccinate between the hours of 9 and 4 any part of the district or at parent's request (Form G). This might necessitate extra visits in an agricultural district like Staines. Return Form H to vaccination officer every month filled in. To keep register. To perform the act of vaccination strictly according to antiseptic conditions and protect with special antiseptic pads. To subsequently attend the child if upset by vaccination free of charge. No less than *ten forms* are now required to carry out the Act—viz., Forms B, C, D, E, F, H, I, O, P, and G. The possibility of being called to attend court to prove visits.

On Dec. 20th, 1898, Mr. Morris appeared before the board of guardians when the fees were unanimously accepted subject to the approval of the Local Government Board. In many districts boards are allowing mileage above the minimum scale, but this, it was considered, would be complex and difficult to adjust.

ASTOUNDING BRITISH ACTION AS TO PLAGUE.

THE news which comes to this country from Calcutta as to the action taken on the East Coast of Africa which is under British jurisdiction, as regards a plague-infected ship, will cause great astonishment, and that feeling will be strongly emphasised by the statement that the action in question has been upheld by the Foreign Office in London. The British India Steam Navigation Company's steamer *Bhandara* was engaged in carrying 1000 coolies from India for the purposes of the Uganda railway and, if report be correct, the authorities at Karachi, the port of departure, took the precaution to examine all the coolies prior to their departure. It is not, however, stated whether the same precautions were taken as regards the crew, concerning whom there is in some ports too much laxity. Twelve days after leaving Karachi the *Bhandara* arrived, on Dec. 27th last, at Kilindini, near Mombasa, and reported seven deaths from plague during the voyage. Here again nothing is as yet stated as to whether the first appearance of the disease was amongst coolies or amongst members of the crew. But peremptory orders were at once issued by the British Governor Sir Arthur H. Hardinge, to the effect that no communication would be allowed with the shore and that the vessel was to return to sea; in brief, an infected vessel was repulsed from British territory and an effort was made to prevent the vessel from getting water at Zanzibar which also comes under British control.

We believe that this action stands unique in modern British sanitary administration. It is in entire violation of everything that England has so long contended for, and, as the Indian Government points out, Great Britain is the first Power to make the Venice Convention a dead letter and hence to lay British shipping open to the same treatment in foreign ports by reason of the precedent she herself has established. The repulsion of an infected vessel has for the last fifty years been condemned in this country as involving distinct cruelty, and in the past it is known to have led to some of the most tragic disasters at sea by reason of the rapid spread of disease amongst those who must remain exposed to infection and because of the lack of food and water on board vessels which had only been provisioned for the purposes of a limited voyage. The story as it is told is too circumstantial for us to doubt the essential facts and we are obliged to admit that we have *read it* with shame. Our only hope is that in the closing days of the year and during a festive season someone at Whitehall has during a temporary absence of his chiefs blundered by commending that which should have been condemned.

It may, of course, be argued that our East African dominions have not formally accepted the Venice Convention. This is, we expect, true. But if the Home Government commend the greatest possible breaches of that Convention in the case of territories under their direct control what becomes of the pressure which they bring to bear on some of our colonies to become parties to the same Convention? Even if the sick had been left on board the *Bhandara* whilst the healthy had been encamped for nine days on shore the matter would have been better. As the story stands it implies gross neglect and unpreparedness at a British port which is known to have long been in constant relations and communication with plague-infected ports of India; and as regards the actual action taken in the case of the unfortunate vessel with her 1000 coolies and crew it seems to be without a solitary redeeming feature.

THE LANCET RELIEF FUND.

TENTH ANNUAL REPORT OF THE ALMONERS.

THE LANCET Relief Fund, which has for its Almoners the President of the Royal College of Physicians of London (Sir SAMUEL WILKS, Bart., M.D. Lond., F.R.S.), the President of the Royal College of Surgeons of England (Sir WILLIAM MACCORMAC, Bart., K.C.V.O.), the President of the General Medical Council (Sir WILLIAM TURNER, M.B. Lond., F.R.C.S. Eng. and Edin., F.R.S.), Mr. THOMAS WAKLEY, F.R.C.S. Eng., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D. Cantab., F.R.C.P. Lond., as Honorary Auditor, came into operation on the 1st of February, 1889.

In presenting the tenth annual report the Almoners think it well again to direct attention to the object for which the Fund was established.

The Fund is sustained solely by the proprietors of THE LANCET who provide every January the sum of at least £300 and is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners or to the widows and orphans of members of the profession in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

When the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established; and as a result the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the desigration of *emergency*, could not be entertained. Attention was called to this fact in THE LANCET of Feb. 16th, 1889, in the following words:—

"We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief"—and who, it may once more be pointed out, are likely to be permanently benefited thereby.

The balance in hand at the end of 1897 amounted to the sum of £173 5*s*. 8*d* On Jan. 3rd, 1898, the Proprietors of THE LANCET placed to the credit of the Fund the sum of £300. During the course of the year repayments of loans to the amount of £15 have been made. The sum of £175 has been granted in relief either by way of loan or of gift, leaving a balance of £318 5*s*. 8*d*. as per bank pass-book.

There have been considered altogether during the twelve months ending Dec. 31st, 1898, 33 applications for relief (the number the previous year having been 37). In 24 cases assistance was awarded either as a loan or as a gift according to the request of the applicant, the amounts of the grants ranging this year from £5 to £25.

The Almoners are glad to find from the number of letters received from recipients of the Fund that it continues to be of service to unfortunate members of the profession and that the particular object of assisting cases of emergency and immediate distress has been attained.

(Signed)

SAMUEL WILKS. WILLIAM TURNER.
WILLIAM MACCORMAC. THOMAS WAKLEY, JUN.
THOMAS WAKLEY.

I find by the Bankers' Book that the actual balance on Jan. 1st, 1898, to the credit of the Fund was £173 5*s*. 8*d*., to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 3rd, 1898.

The balance at the Bank at the present date is the sum of £318 5*s*. 8*d*. I have also checked the receipts for disbursements and find the above account strictly accurate.

December 30th, 1898. HENRY A. PITMAN, Hon. Auditor.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5467 births and 4105 deaths were registered during the week ending Dec. 31st. The annual rate of mortality in these towns, which had been 16·6 and 17·8 per 1000 in the two preceding weeks, further rose last week to 19·1. In London the rate was 18·4 per 1000, while it averaged 19·5 in the thirty-two large provincial towns. The lowest death-rates in these towns were 12·6 in Croydon, 13·7 in Huddersfield, 14·1 in Cardiff, and 14·6 in Halifax; the highest rates were 23·5 in Blackburn, 23·6 in Oldham, 24·3 in Wolverhampton, and 24·6 in Gateshead. The 4105 deaths in these towns included 405 which were referred to the principal zymotic diseases, against 372 and 424 in the two preceding weeks; of these 106 resulted from diphtheria, 95 from measles, 71 from whooping-cough, 63 from "fever" (principally enteric), 36 from diarrhœa; paid 4[illegible] from scarlet fever. No death from any of these w[illegible]mber pes recorded last week in Birkenhead; in the other and 34 [illegible] value caused the lowest death-rates in Plymouth, diseases wa[illegible]n, with nd, and Newcastle-upon-Tyne, and the towns they ca[illegible]e than Wolverhampton, Gateshead, Nottingham, Bristol, Sunderla[illegible]ndite greatest mortality from measles occurred highest rates in [illegible]ofhester, Nottingham, and Swansea; from and Swansea. Th[illegible]n, Swansea, Huddersfield, Gateshead, in Salford, Manc[illegible]n; and from "fever" in Derby, Bolton, whooping-cough [illegible]ne mortality from scarlet fever showed no Oldham, and Presto[illegible]y of the large towns. The 106 deaths nd Gateshead. Th[illegible]icuded 47 in London, 8 in West Ham, marked excess in m[illegible]ticmingham, 5 in Swansea, 5 in Liverpool, om diphtheria incl[illegible]t, in Leeds. No fatal case of small-pox in Sheffield, 6 in Bi[illegible] in Leicester, and 4 [illegible]ng the week under notice either in was registered durir[illegible]ssof the thirty-three great towns, and London or in any o[illegible] no small-pox patients [illegible]rofe were under treatment in any of the Metropolitan Asylu[illegible]ough ms Hospitals. The number of scarlet fever patients in [illegible]fu these hospitals and in the London Fever Hospital on Saturday last, Dec. 31st, was 2939, against numbers decses fair. end of the six prec dispen[illegible]ning from 3259 to 2901 at the preceding weeks; 225 new cases were admitted during the ostra week, against 276, 260, and 264 in the three preceding weekica. The deaths referred to diseases of the respiratory organs [illegible] in London, which had been 283 and 284 in the two preceding weeks, further rose to 306 last week, but were 291 below the co[illegible]rrected average. The causes of 60, or 1·5 per cent., of the de[illegible]aths in the thirty-three towns were not certified, either b[illegible]y a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Manc[illegible]hester, Salford, Newcastle-upon-Tyne, and in thirteen othe[illegible] smaller towns; the largest proportions of uncertified death[illegible]s were registered in Birmingham, Liverpool, Bradford, and H[illegible]ull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in [illegible] which had declined in the [illegible]meeti[illegible]he eight Scotch towns, 21·0 to 18·2 per 1000, was athree preceding weeks from ending Dec. 31st., and wa be ragain 18·2 during the week rate during the sam[illegible]hich is 0·9 per 1000 below the mean English towns. The period in the thirty-three large ranged from General the rates in the eigh Scotch towns [illegible] 12·4 in Paisley and 17·4 in Dundee to 21·3 in Greenock and 22·1 in Perth. The 548 deaths in these towns included 14 which were referred to whooping-cough, 13 to measles, 10 to scarlet fever, 9 to diarrhœa, 9 to "fever" (principally enteric), and 3 to diphtheria. In all, 58 deaths resulted from these principal zymotic diseases, against 54 and 68 in the two preceding weeks. These 58 deaths were equal to an annual rate of 1·9 per 1000, which corresponded with the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 16 and 14 in the two preceding weeks, were again 14 last week, of which 7 occurred in Glasgow, 3 in Edinburgh, and 3 in Aberdeen. The 13 deaths from measles showed a slight further increase upon recent weekly numbers, and included 6 in Glasgow and 4 in Edinburgh. The fatal cases of scarlet fever, which had increased from 5 to 14 in the five preceding weeks, declined to 10 last week, of which 6 occurred in Glasgow and 3 in Dundee. The 9 deaths referred to different forms of "fever" were within 2 of the number in the preceding week, and included 5 in Glasgow and 2 in Edinburgh. The deaths from diseases of the respiratory organs in these eight towns, which had been 132 and 119 in the two preceding weeks, further declined to 110 last week, and were 76 below the number in the corresponding period of last year. The causes of 26, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·2 per 1000 in each of the two preceding weeks, rose to 27·7 during the week ending Dec. 31st. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 26·8 per 1000, the rate during the same period being 17·2 in London and 20·0 in Edinburgh. The 186 deaths registered in Dublin during the week under notice showed an increase of 17 upon the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 15 and 10 in the two preceding weeks; of these, 4 resulted from whooping-cough, 2 from diarrhœa, 1 from scarlet fever, 1 from diphtheria, and 1 from "fever," but not one either from small-pox or measles. These 9 deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 1·8 in London and 1·9 in Edinburgh. The fatal cases of whooping-cough, which had been 5 and 4 in the two preceding weeks, were again 4 last week. The mortality from "fever" also corresponded with that recorded in the preceding week; while the mortality from scarlet fever showed a decline. The 186 deaths registered in Dublin last week included 38 of infants under one year of age and 44 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded the numbers recorded in the preceding week. Twelve inquest cases and 8 deaths from violence were registered; and 73, or more than a third, of the deaths occurred in public institutions. The causes of 19, or more than 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

STAFF SURGEON SAMUEL WILLIAM VASEY has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

The following appointments are announced:—Staff Surgeons: Graham E. Kennedy to the *Liffey*; Edward J. Morley to the *President*; Charles W. Sharples to the *Australia*, for R.N. Rendezvous and Medical Depôt; and Vidal G. Thorpe to the *Furious*.

ROYAL ARMY MEDICAL CORPS.

Major J. J. C. Donnet proceeds from Poona to Rawul Pindi for temporary duty in the Punjab Command. Captain H. A. Bray and Captain J. H. Rivers, now in India, proceed to Cairo for service with the Egyptian Army on the Nile. Majors J. J. O'Donnell, R. O. Cusack, A. O. Geoghegan, and F. B. Maclean, Captain S. J. Perry, and Lieutenant S. O. Hall have left England in the *Dilwara* for India; Major O. W. Allport is *en route* to Malta in the *Jelunga*, and Captain W. E. Hardy is *en route* to Cape Town in the *Goorkha*.

INDIA AND THE INDIAN MEDICAL SERVICES.

Colonel Eaton, Royal Army Medical Corps, Principal Medical Officer, Poona District, having been directed to proceed from Poona to Nowshera to assume the duties of Principal Medical Officer, Malakand Field Force, Lieutenant-Colonel W. J. Fawcett, Royal Army Medical Corps, takes charge of the office of Principal Medical Officer, Poona District, in addition to his own duties.

The Queen has approved of the following promotion:—To be Colonel: Lieutenant-Colonel William McConaghy, Bombay Establishment. The Queen has also approved of the retirement from the service of the under-mentioned officers:—Lieutenant-Colonel Frederick Henry Blenkinsop, Madras Establishment; Brigade-Surgeon-Lieutenant-Colonel Frederick Augustus Smyth, Bengal Establishment; and Lieutenant-Colonel Phirozsha Jamsetji Damania, Bombay Establishment.

VOLUNTEER MEDICAL STAFF CORPS.

Captain Lewis Way, Royal Army Medical Corps, to be Adjutant, vice Captain G. T. Rawnsley, whose period of service has expired. Surgeon-Captain B. Locking to be Medical Officer to the 3rd Battalion, Wellington (East Coast) Rifle Volunteers, with present rank.

ARMY MEDICAL STAFF AND ROYAL ARMY MEDICAL CORPS.

The following retirements will take place during the present year:—Surgeon-General A. F. Churchill, June 14th; Surgeon-General T. Maunsell, C.B. July 1st; Surgeon-General W. Nash, Nov. 20th; Colonel R. P. Ferguson, March 13th; and Lieutenant-Colonel A. H. Anthonisz, Dec. 22nd.

THE NEW YEAR HONOURS.

The following officers of the Indian Medical Service are included in the New Year's Honours' list: Colonel William Pleace Warburton, M.D. Edin., and Colonel David Sinclair, M.D. Aberd., receive Companionships of the Order of the Star of India, and Lieutenant-Colonel Henry Kellock McKay, M.R.C.S. Eng., and Major Winthrop Benjamin Browning, L.R.C.P. & S. Irel., Companionships of the Order of the Indian Empire; Captain John Lloyd Thomas Jones, M.B. Durh., Captain William Ernest Jennings, M.B. Edin., Captain Arthur Frederick William King, M.R.C.S. Eng., L.R.C.P. Lond., and Lieutenant William James Niblock, M.B. R.U.I., are to be enrolled as Honorary Associates of the Order of the Hospital of St. John of Jerusalem in England.

BADGE FOR THE ROYAL ARMY MEDICAL CORPS.

The *Daily Mail* of the 3rd inst. has the following announcement:—The military headquarters and the Herald's College of Arms have designed a badge for the newly-formed Royal Army Medical Corps which now comprises all ranks of the old Army Hospital Corps and the Medical Staff Corps. From time immemorial the serpent and rod have been the emblem of the art and practice of medicine, and it has therefore been decided to make the serpent the future badge of the Royal Army Medical Corps. The serpent is entwined round a caduceus enclosed in a laurel wreath surmounted by the Imperial crown, with the motto, "In arduis fidelis."

THE EXAMINATION FOR THE ARMY MEDICAL SERVICES.

The result of the next competitive examination for the Royal Army Medical Corps and Indian Medical Service is awaited with great interest as medical officers are much needed to fill up the establishment and relieve the pressure on medical officers at present serving in the Royal Army Medical Corps especially.

DEATHS IN THE SERVICES.

Surgeon-General L. S. Bruce, retired, at Ealing, aged sixty-eight.

Correspondence.

"Audi alteram partem."

"WHAT IS TABES MESENTERICA IN INFANTS?"

To the Editors of THE LANCET.

SIRS,—Dr. J. W. Carr's letter in THE LANCET of Dec. 17th raises the interesting question how far infection of infants with tubercle really takes place through the alimentary in comparison with the respiratory tract. I cannot quote statistics such as his but I can thoroughly endorse what he says as to the too free use of the expression "consumptive bowels" by the class of parents who bring their children to hospitals. Over and over again I have been asked, when seeing a wasted infant half killed by improper feeding, but presenting no evidence whatever of tubercle either of the abdominal or thoracic organs, "Do you think baby is suffering from 'consumptive bowels'?" Ask the mother why she has this idea and she replies, "My doctor told me so"; and she is obviously dissatisfied with the statement that there is no evidence of "consumptive bowels" but much evidence of her own ignorance and possibly of neglect. Clearly, as Dr. Carr says, the condemnation to death under the phrase "consumptive bowels" has satisfied everyone and exonerated both parents and medical man from any further effort to preserve the child's life; and yet over and over again such a child, if not too much enfeebled, has recovered on admission to hospital, where the only treatment has been rational feeding and where no sign of tubercle has ever shown itself. Such cases, I am sure, help to swell largely the Registrar-General's death returns of abdominal tuberculosis, particularly in the class under one year, and to vitiate any argument based on the alleged increase of "tabes mesenterica."

There is another matter which I think has been strangely overlooked in the question of infection by tuberculous milk which now occupies so prominent a place in our medical and lay journals. It seems to be generally assumed that the children of our poor are fed upon "raw" milk. We as a nation are even held up to opprobrium for our habit of giving uncooked and therefore possibly tuberculous milk to children. It is generally assumed that while the children of the well-to-do are fairly carefully guarded against such infection by their milk being boiled, the children of the poor are perpetually exposed to this danger by being fed on "raw milk." My own experience is that the poor almost invariably when using fresh milk boil their pint or two pints *as soon as they receive it.* At the North-Eastern Hospital for Children I have asked the question in hundreds and hundreds of cases, "Are you careful to boil the milk before giving it to your baby?" I can hardly remember a single instance where the answer has been in the negative, and a moment's reflection will show that these people are speaking the truth. In their small hot rooms it is not easy to preserve milk for many hours, particularly in the summer, and therefore they are forced into taking the best course known to them for preserving the milk—namely, boiling. I quite believe that the milk which has been boiled in the morning is often exposed before use to fresh infection, but this is very rarely tuberculous.

It is generally admitted that boiling or even Pasteurising at 167° F. will render tuberculous milk safe, and if this be so and my contention as to the boiling of the great bulk of the cows' milk used for infant feeding in our big towns is also true, then we do away with the argument that the alleged increase in tabes mesenterica is due to milk infection and we may well follow out Dr. Carr's inquiry as to whether tabes mesenterica is really so common a disease, as a ready acceptance of the Registrar-General's returns might lead one to believe. I do not for one moment suggest that the precautions advocated in Sir William Broadbent's speech at Marlborough House as to rejection of tuberculous cows as milk suppliers should not be carried out, but I feel that if there is any increase in tuberculous mesenteric disease, which I consider very doubtful, the causes must be sought for elsewhere than in our milk-supply. For even that pernicious article "condensed milk," so largely used among the poor from its cheapness, convenience, and its palatability (to infants' taste), has undergone sterilisation at 212° F. previously to its condensation and is therefore presumably harmless from a tuberculous point of view. If official supervision be exercised over our own dairy cows and the tuberculous ones be excluded as milk-suppliers it is earnestly to be hoped that the very large and increasing quantity of foreign fresh milk imported will be subjected to a rigid bacteriological scrutiny which will make it impossible for tuberculous foreign milk to undersell pure English milk whose cost must almost necessarily be raised by the restrictions on its supply involved by a rejection of tuberculous dairy cows. I am, Sirs, yours faithfully,

Lower Seymour-street, W., Dec. 30th, 1898. W. A. WILLS.

"THE SEAMEN'S HOSPITAL SOCIETY AND ITS VISITING STAFF."

To the Editors of THE LANCET.

SIRS,—Dr. Manson's impressions as to his position on the staff of the Seamen's Hospital Society as set forth in his letter in THE LANCET of Dec. 31st are so mistaken that we are again obliged to draw his attention to the written records on the subject.

On April 9th, 16th, and 23rd, 1892, advertisements appeared in the medical press (THE LANCET and *British Medical Journal*) for a visiting physician to the Seamen's Hospital Society's Branch Hospital, Victoria and Albert Docks. Dr. Manson was a candidate for this post. He was selected on May 4th by a sub-committee of which we were members and duly elected on May 13th to the appointment he sought. Reference to the minute-book to which we referred him clearly shows this. It was some considerable time after Dr. Manson was appointed to the Branch Hospital that the physicians of the *Dreadnought* as an act of courtesy to him allowed him the use of 6 beds in their wards for cases which had been under his care at the Branch. They both lent him 3 beds, little supposing that this concession would lead him to assume the title of "Physician to the Seamen's Hospital, Greenwich."

The annexed letter from us to Dr. Manson (Jan. 21st, 1896) clearly put before him his real position, yet after his apology (copy of which is enclosed) he now writes: "At the time of the correspondence referred to I did consider, as I still consider, that I had a perfect right—in fact, as much right as either Dr. Curnow or Dr. Anderson had—to designate myself 'Physician to the Seamen's Hospital, Greenwich.'" The profession must judge whether it is "in conformity with medical custom" for a physician elected to one hospital to describe himself as physician to another and whether the officers of the latter have not cause for remonstrance if such is repeatedly done.

We are, Sirs, your obedient servants,
JOHN CURNOW.
JOHN ANDERSON.
Jan. 3rd, 1899. G. R. TURNER.

[*Copy of Letter from the Staff of the Seamen's Hospital to Dr. Manson.*]

Dreadnought Seamen's Hospital, Greenwich,
21st January, 1896.

DEAR DR. MANSON,—With reference to your letter to Mr. Michelli of the 18th Dec. last, a copy of which has been sent to one of us and which we should have replied to sooner but for the Christmas holidays, we wish to draw your attention to the terms of your appointment as shown in the minute-book of the Seamen's Hospital Society.

On May 4th, 1892, a sub-committee met to recommend a physician to the Branch Seamen's Hospital at the Royal Victoria and Albert Docks and an ophthalmic surgeon to the Seamen's Hospital Society. In the same minute-book (May 13th, 1892, page 138) it is noted that you were elected to the office of physician to the said branch hospital and Mr. Gunn ophthalmic surgeon to the Seamen's Hospital Society. We also wish to call your attention to the 74th official report of the Seamen's Hospital Society (copy enclosed) in which you are styled Physician to the Royal Victoria and Albert Docks' Hospital and to the official note-paper in which a distinction is clearly drawn between the *Dreadnought* Seamen's Hospital, Greenwich (235 beds), and the Branch Seamen's Hospital, Royal Victoria and Albert Docks (18 beds).

It appears clear to us from the foregoing that you should not allow yourself to be described as "Physician to the Seamen's Hospital, Greenwich," as has lately been done in the list of contributors to Davidson's "Hygiene and Diseases of Warm Climates," the *British Medical Journal*, Kelly's London Medical Directory, 1895, and Churchill's Medical Directory, 1896. If there is still any misunderstanding we shall be happy to meet you and discuss the matter. We are forwarding a copy of this letter to Mr. Michelli.

We remain, yours faithfully,
(Signed) JOHN CURNOW, } Visiting Physicians.
JOHN ANDERSON, }
G. R. TURNER, Visiting Surgeon.

[*Copy of Letter from Dr. Manson to Mr. W. Johnson Smith.*]

21, Queen Anne-street, Cavendish-square,
4th Feb., 1896.

DEAR MR. JOHNSON SMITH,—Many thanks for your very courteous letter.

Your interpretation of mine to Mr. Michelli is correct. Therein I explained how I came to call and allow myself to be called "Physician to the Seamen's Hospital, Greenwich," a mistake I shall be careful to avoid in future. Please accept and convey my apologies to the medical staff.

Yours very truly,
(Signed) PATRICK MANSON.

"TWO CASES OF CÆSAREAN SECTION" (ON ACCOUNT OF IMPACTED OVARIAN TUMOUR).

To the Editors of THE LANCET.

SIRS,—Dr. Braithwaite publishes in your issue of Dec. 31st two cases in which he successfully performed Cæsarean section on account of ovarian tumour impacted in the pelvis during advanced pregnancy. As Cæsarean section has been performed several times of late on account of this condition I would beg a little of your space to point out that an impacted ovarian tumour is not an indication for this severe operation which in addition to its immediate danger entails some risk of rupture of the uterus in a subsequent pregnancy and of the formation of calculi if the uterine sutures work their way into the bladder. Not to mention removal of the tumour by the vagina (which personally I do not favour), the difficulty may be got over either by reposition of the tumour or, if that be impossible or inadvisable, by slightly[1] enlarging the abdominal incision and withdrawing the uterus from the abdomen and then removing the tumour and replacing the uterus, first delivering the child by the vagina if the cervix be dilated during labour. During the last two years I have met with 4 cases of incarcerated ovarian tumour during pregnancy, which I have removed by simple abdominal ovariotomy. In one case I removed the tumour during pregnancy, in two others pushed it up and removed it after delivery, and in the fourth removed it during labour by the last method mentioned above. The mothers and children all survived. In Dr. Braithwaite's second case I notice that the child (which subsequently died) was removed shoulder first, but as the child can only be delivered in this position through an unnecessarily large *incision and with increased danger to its* life it would seem to be better to follow the practice of ordinary midwifery and deliver by version (preferably cephalic). I am, Sirs, yours faithfully,

Harley-street, W., Jan. 2nd, 1899. HERBERT R. SPENCER.

"DIPHTHERIA ANTITOXIN IN PRIVATE PRACTICE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 24th, 1898, page 1733, there appears a letter on Anti-diphtheritic Serum signed "H. E. G." This writer raises two important points—viz., dose and price; and as he mentions us by name kindly permit us a word in reply. First as to dose. He puts the number of antitoxin units used at the hospital where he worked and of which he was assistant medical officer as "not uncommonly from 8000 to 16,000, and even 24,000 in forty-eight hours, with the result "that he was so convinced of the good obtained that when he took up private practice he determined to adopt it." Very satisfactory. "H. E. G.'s" experience corroborates that of Dr. Sidney Martin as detailed by him in the *British Medical Journal* of Sept. 3rd, 1898, and no one so far as we know has had greater success than he at University College Hospital. His average dose now is 6000 units; but at a *tentative time* doubtless he prescribed many more. His low rate of mortality has encouraged others, so that it would be true to say that the dose of antitoxin has a tendency upwards. Some bacteriologists believe that failures in its use three or four years ago were probably due in many instances to the antitoxin being too weak and being administered in an impotent dose; and as medical men become converted to the views propounded by Dr. Martin and endorsed by your correspondent "H. E. G." so will the mortality from diphtheria in all probability fall to almost vanishing point. And therefore we think that great service has been rendered by the attention of the profession being drawn to the proper doses of serum.

Till recently it has been impossible to obtain very strong serum commercially, but now *with a serum containing* 1250 units per c.c. it is possible to administer in 4½ c.c. (about 2 drachms) a dose of 6000 units. Our serum is tested and certified by one of the highest bodies in the land; it will retain its potency for months, and there is no difficulty about "stocking" it either on the part of local chemists or of medical men themselves.

"H. E. G." has done us an injustice, no doubt unintentionally, in quoting our price as 17*s.* 6*d.* for 2000 units. Our charge is 6*d.* per 100 units, at which figure it has stood for *eight months* past; and considering all that is stated above we consider it a fair one.

We enclose herewith our circular letter concerning serum-therapy and our price list of serum. Kindly forward it to "H. E. G." with our assurance that both have been *circulated* for many months past.

We shall be most pleased to answer questions.

We are, Sirs, yours faithfully,
PARKE, DAVIS, AND CO.

North Audley-street, W., Dec. 28th, 1898.

To the Editors of THE LANCET.

SIRS,—I would venture to suggest that your correspondent

---

[1] It is remarkable through how small an incision the uterus can be delivered if it be tilted so that one cornu presents and the abdominal wall be pulled back over the uterus instead of trying to lift the organ out of the abdomen.

"H F G in The Lancet of Dec 24th 1898 must have made a mistake in his figures For 16,000 units read 1600, and I think the latter figures will represent the dose of serum usually recommended in all but the severest and most unfavourable cases Probably this is only a clerical error, but I can imagine many a country practitioner might be deterred from using the serum by the cost so large a dose would involve I have had several most successful cases and have never had to use more than 1500 units

I am, Sirs, yours faithfully,
G M P

Dec. 28th 1898.

Erratum —In Mr H F Allen's letter published in our issue of Dec 24th an asterisk should have appeared before the name of the Royal College of Surgeons in Ireland, indicating that the preliminary examination of this body is no longer on the General Medical Council's list

THE IRISH LOCAL GOVERNMENT ACT

(From our Special Commissioner)

Sanitation and the Dispensary Medical Officers

The new law for the local government of Ireland will come into force on the 25th of March this year The question naturally arises as to the effect which this most recent phase of Irish legislation is likely to have upon the position of the medical officers of dispensaries This large class of practitioners suffer from grievances which are closely akin to those denounced in The Lancet under the headings of "The Battle of the Clubs and "Hospital Abuse But the position of the Irish dispensary medical officer is often more hopeless As Ireland is mainly an agricultural country there are but few large towns Therefore medical practices are principally rural, the populations are very poor so that the dispensary medical officer is dependent on his salary and cannot hope to acquire a private practice of sufficient importance to make him independent of his appointment There are 159 unions in Ireland Each union has its board of guardians, its workhouse hospital or infirmary and a medical man attached who as a rule only attends to the hospital patients These union districts are, however, very large and have consequently been subdivided into 893 dispensary districts Each dispensary district has its dispensary committee which is under the jurisdiction of the board of guardians and some guardians may attend the meetings of such committees *ex officio* The dispensary committee is a very small local body In the rural districts—and these constitute the vast majority of the districts—there are but few educated persons who could possibly be chosen as committee men These nominations are made by the board of guardians and the nominee must have a rating of £30 a year The committee is supposed to meet at least once a month but its members do not always observe this rule and are far more ready to come together for election and political purposes than for the carrying out of dispensary business The committee men are largely selected from the petty tradesmen and small farmer class They are very generally chosen for political reasons, many do not even know how to read but they have influence in keeping together the political party which nominates them Sometimes a justice of the peace may be appointed but very often he does not reside in the district and therefore does not attend Stupid, uneducated farmers and illiterate pothouse politicians who cannot even sign their names are put on these dispensary committees They have no knowledge of public duties and of local administration All they can do is to rail against the Jesuits if it be a Protestant district and to abuse the Saxon domination if it be a Roman Catholic district Yet it is these miserable petty local committees where the ignorant prejudices and fanaticism of either Protestant or Roman Catholic, according to the district govern all other considerations which have had the mission to select and appoint the dispensary medical officers Certainly the Irish Local Government Board defines what should be the qualification of the medical man—i e a knowledge of medicine surgery, and midwifery—but it is the dispensary committee which selects among qualified candidates the medical man it prefers

What, then, has a medical men to do so as to secure his election by such a committee? First and foremost he must pay court to the leading local priest or minister It is of absolutely no use striving unless he is in religious accord with the majority of the district He must be Presbyterian with the Presbyterians and Roman Catholic with the Roman Catholics or his chances are *nil* Then he must have the same political opinions as the members of the dispensary committee, and though as a rule Roman Catholics are Nationalists and Protestants are Unionists this is not always the case Nor does the difficulty end here In some districts the successful candidate has been elected on the strength of being a boon companion which is not altogether the best qualification for attending upon the sick poor When a vacancy occurs there is, unfortunately and in spite of these degrading conditions a great rush of candidates Perhaps as many as twelve medical men will apply for the vacant post Invariably the first question asked relates not to the experience or capacities of the candidate but to his religious opinions This inquisition is equally strict on both sides The Protestants are just as prejudiced and unfair as are the Roman Catholics As a dispensary medical officer put it to me, "The candidate must square the parish priest or the Tory landlord, otherwise he has not the ghost of a chance Then to succeed he should be a friend or relation of one or more of the members of the committee or of the parish priest The committee will not inquire about the candidate's technical capacities, his success as a practitioner is the last of all considerations, they will scarcely inquire if he is sober Indeed there are cases of persons to whom the Local Government Board have taken objection and who have nevertheless been re elected by these dispensary committees The election is reported by the dispensary committee to the board of guardians and by the latter to the Local Government Board, which final authority always confirms the election unless the candidate had been on a previous occasion dismissed from the Poor law service

The dispensary medical officer has not only to attend to the sick poor but as a rule he is also the medical officer of health of the district, the public vaccinator and the registrar of births deaths and marriages It is bad enough that the attendance on the sick poor should depend upon such a method of election as that thus described but the general public health is likewise imperilled The dispensary committees consist for the most part of a class of men who know nothing and care less about sanitary matters They are dirty and careless in their habits and if the dispensary medical officer were to do his duty as medical officer of health he would have to report against the very committee men who had appointed him Then in rural districts the dispensary medical officer receives perhaps only £10 a year for his work as medical officer of health The practical result is that nothing is done and no attempt is made to alter even the most flagrant insanitary conditions The Irish Medical Association has sought in vain to improve this deplorable state of affairs Deputations were sent to London before the Irish Sanitary Act was passed They induced Sir Michael Hicks Beach to introduce a clause in the Bill appointing superintendent medical officers of health for all Ireland who were to see that the local medical officers of health did their duty The deputation returned from London delighted with the result of their mission But when the Bill had become law the Local Government Board of Ireland set to work to neutralise its effects Instead of insisting at once on the appointment of competent superintendent medical officers of health a circular was sent round to the boards of guardians saying that in appointing medical officers of health no salaries would be sanctioned which exceeded in amount a quarter of the sum paid to the local dispensary medical officer This meant that the latter whenever appointed to act as medical officer of health could rarely obtain more than £25 and generally only about £12 or £15 a year for performing these extra duties The guardians and the dispensary committees being for the most part diametrically opposed to any sort of sanitary reform in many cases did not offer even this small amount so that there was practically every inducement for a medical officer of health who wished to get on with his Board to leave matters alone With regard to the superintendent medical officers of health who were to put an end to this systematic negligence the Irish Local Government Board commenced by issuing a circular altering the name of the office to that of "consulting sanitary officer By this it was inferred that they were not to act unless they were consulted. Naturally it was well known that they were never likely to be consulted. But further, to make it still more certain that they should do nothing it was laid down that they were to receive no salary whatsoever. They might, it is true, be paid a guinea per consultation when consulted, and of course this possibility of having to pay a guinea was another very good method of preventing any effective sort of superintendence being exercised. Thus public health questions remain in abeyance and it may be said that so far as the rural districts and the small towns are concerned medical officers of health exist only in name.

The question now arises whether under the new Local Government Act any improvement will take place. The Act abolishes the local dispensary committees. The districts will remain but the appointments of dispensary medical officers to those districts will be made by the boards of guardians. These being larger and more important bodies it is supposed that they will be less amenable to corrupt and petty local influences. On the other hand the *ex-officio* guardians have been abolished. They consisted of the largest ratepayers and property-owners of the neighbourhood who sat on the board of guardians without being elected. This gave a certain tone to these bodies. Now all the guardians must be elected, so they will all be strict party men. These new boards of guardians will, it is supposed, be controlled, at least to some extent, by the district councils representing a federation of five unions. Again, the district councils are in their turn to be controlled by the county councils. But the functions of these various authorities differ greatly and it is thought that the control they will exercise will prove to be very slight. Opinions are much divided as to the probable result. Some think there will be an improvement; others, on the contrary, maintain that the present grievances will, if anything, be accentuated.

So far as the interests of the public are concerned the first and most urgent reform needed is that the appointment of dispensary medical officers and medical officers of health should depend wholly on the ability of the candidates to fulfil the duties involved and not on their political or religious opinions. The neutralising of such offices would certainly be quite contrary to the spirit and inclinations of the Irish people whether Protestant or Roman Catholic, but it is nevertheless most necessary. To what length political and religious antagonism may go is best shown by a most melancholy story related to me. A dispensary medical officer had reached the age of eighty-two years. For several years he had been quite unfit for his work. He was called up at all hours of the night and sometimes he had to see patients who lived at a distance of eight miles, but more often than not the patients had to do without him. Not only was he weak, old, and infirm, but he was partially blind. Still he kept on as long as was possible, striving to do his work, as he was dependent solely on his salary for his subsistence. At last three members of his dispensary committee called upon him and promised that if he resigned they would persuade the committee to grant him a pension. Though advised by his friends not to accede to this request the medical officer, feeling that he had no longer the strength to attend properly to his patients, finally tendered his resignation. He thus placed himself at the mercy of the committee, for he had only the promise and not the certainty of a pension. The three committee-men who had seen him before now called again. They repeated their promise to get him a pension but explained that they were unable to do so for the moment because it had been discovered that he had not resigned his post as medical officer to the constabulary. He must also resign that function so that they might have more to offer to the new dispensary medical officer who had soon to be appointed. In vain the aged practitioner protested that this was his last source of income and that if he gave it up and they failed to obtain the promised pension he would be reduced to beggary; still they insisted and finally he complied. No sooner had this been done than the three members of the dispensary committee, instead of keeping their promise and using all their influence to prevail upon the committee to vote a pension, sought, on the contrary, with all their force to oppose the proposal to grant the pension. They explained that they had persuaded the old man to resign so as to get rid of him. His daughter had accepted a seat on an "outside car" to drive to the local railway station to see the train pass which bore the Prince of Wales on his way to Cork. This was an insult to the Nationalism of the committee and therefore the dispensary medical officer, after years of faithful service, was treacherously persuaded to resign. He was left to starve, and did not get any pension whatever, because his daughter had tried to see the Prince of Wales.

But in such cruelty and heartlessness the Roman Catholics are not alone. The Protestants can be guilty of equal inhumanity. Thus the story was told me of another dispensary medical officer serving a Protestant dispensary committee in the north of Ireland. He was very old and he suffered acutely from "rheumatic gout." He had to drive to his patients and when on reaching a village he arrived at the cottage where they were waiting for him the patients came out one by one and stood on the sidewalk. He questioned and examined them as best he could without leaving his trap. He had served this district for forty years, yet his committee would not give him a pension nor would they pay for a locum-tenent. At last he had to ask his son to help him, though his son had a dispensary district of his own situated six miles away. With this aid he continued the work for two years more and then died in harness. What are we to think of a local authority which can be guilty of such cruel and petty economy?

The new Act deals with the question of pensions but in a most unsatisfactory manner. All dispensary medical officers who are sixty years old on March 25th, 1899, and have worked in that capacity for twenty years will get a pension equal to one-third of their salary. This they will obtain whether the guardians approve or not. But after this one settlement the old and vicious system comes in force again. Dispensary medical officers will once more depend on the boards of guardians for their pensions. These boards will be able to refuse to give any pension whatsoever or they may give as much or as little as they choose. Thus the improvement effected by the Act will have but a transitory effect.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

A New System of Administration of Plague Measures.—The Proceedings of the Plague Commission.—The City of Bangalore.

THE drastic measures originally carried out with the idea of controlling the plague epidemic have been gradually relaxed. With the recognition of their failure to limit the disease the Government have now gone to the other extreme. Amongst other things they have concluded that to make hospitals effective it is necessary to secure the confidence of the classes for whose succour they are built and maintained. Having found that even with house-to-house visitation fully 50 per cent. of cases were successfully concealed the Government have now decided to encourage the voluntary reporting of cases. This is hoped to be achieved by making the hospitals attractive and by taking measures to eliminate the lesser discomforts and loss resulting from disinfection and to obviate the hardship of the temporary removal of the poorer classes of people from infected houses and streets. It is supposed that so long as hospitals are regarded with suspicion and dislike there will be concealment of cases and opposition to removal. The hospitals are to be ornamented with plants and flowers and hakims and native practitioners may be employed by the patients. The sufferings of the poor whose normal poverty is sadly aggravated by the visitation of plague are to be mitigated by the support of the family of the sufferer during the incapacity of the bread-winner, by the payment of funeral expenses if death supervenes, by the provision of extra rations for a few days before the discharge of the convalescent, and by assistance to such to return to their families. To obviate concealment of cases through dread of disinfection compensation on the spot will be made to the poor for destruction of any clothing and a sum will be handed over to meet the expense of removal during a temporary vacation of their house and transfer to a camp. A blanket is to be given and in special cases a charpoy will be provided. For these purposes of so-called discretional relief there will be officers appointed. This administration of plague measures sounds very kind and charitable and certainly contrasts very strongly with that which has been done before. It took many years in

England before the working classes got over their aversion to enter the hospitals and it is not likely that the passive opposition to all plague measures by which the natives express their dislike will be overcome very readily.

A notice prohibiting the passage of suspicious persons to Malabar Hill and the neighbourhood has been published in the Government *Gazette*. Plague authorities specially appointed by the Municipal Commissioner of Bombay for the purpose are authorised to prevent the passage of suspicious persons and their clothing, baggage, &c., into the local area defined. As the value of even a rigid medical inspection of all travellers is very limited it is manifest that an order of the above character where there is no cordon round the area concerned or medical inspection of persons entering it is practically worthless.

Acting on the assumption that the rat is an active agent in propagating plague the Health Department in Bombay city have organised a systematic destruction of rats. Last week 5263 were destroyed. After the first outbreak the rat population was nearly exterminated. In the interval before the next outbreak this rat population was partially regenerated but was again reduced by the recrudescence of plague last spring. For some months past it has been evident that the normal rat population of Bombay was fast returning and the finding of considerable numbers of dead and dying rats in certain parts was regarded with apprehension.

The Plague Commission opened its sittings at Bangalore on Dec. 12th. Colonel Robertson, the British resident, was first examined. He described the course of the outbreak and the ordinary recognised measures which were adopted. He referred to the difficulties of administration due to the stress of work and to the strikes and to the troubles about the water-supply. The police and military aid had been invoked because a certain show of force was required to support the medical officers whom it was hazardous to send into the bazaars inadequately escorted. He also referred to the general opposition to plague measures. Captain Roe, R.E., the chief plague officer of the cantonment, was the next witness examined. He thought that segregation had been a failure. When a case was reported he found that half the people of the house ran away. The fear of the natives was due to the dread of disinfection and the loss of property. Major Deane, R.A.M.C., could not say that infection could be conveyed one way more than another. He thought that people attending plague patients in hospitals might carry infection through their clothing. Colonel T. McGann gave evidence concerning inoculation in the district. Colonel Dobson, I.M.S., referred to various antiseptics which had been used. He had noticed that plague ran a milder course amongst inoculated persons. He thought that no special treatment by drugs served to do any good. The proceedings of the Plague Commission not being open to the public information concerning the evidence tendered is only available through the press, but it is possible to cull the chief points of medical interest from the reports published. So far the information obtained is very unsatisfactory, and the evidence may be described as merely the brief verbal report of plague officials brought up to date.

The city of Bangalore, with a population of 60,000 persons, seems to have suffered very severely from plague. Up to Dec. 2nd there had been 2985 cases and 2361 deaths. The highest total on one day was reached on Nov. 11th, when 122 cases were reported. The plague is making serious headway in the adjacent towns. Madras city gets a few cases imported from time to time. Up to date 4609 persons have been inoculated there.

The promulgation of new rules by the Mysore Durbar has given great impetus to inoculation, some 18,000 persons having been operated upon in the city of Mysore during the past two weeks. There are no less than 150 prisoners to be tried in connexion with the plague riots in Seringapatam.

The Bombay Presidency returns are more favourable. From 4604 attacks and 3690 deaths two weeks ago the figures have fallen to 3923 attacks and 3178 deaths. It will be seen that the death-rate still keeps at about 75 per cent. The total number of cases since September, 1896, is 196,458, and the deaths 155,054. There has been a slight but steady increase in the number of cases in Bombay city during the past three weeks, the deaths for last week from plague being 61. Karachi still occasionally reports a few cases. A few cases have also been again imported into Poona. In Satara the attacks have increased from 310 to 405 and the deaths from 264 to 321. In the Dharwar district the epidemic appears to be rapidly declining. Kolapur reports 548 attacks and 433 deaths, as against 622 attacks and 478 deaths the week previously. There are still 378 infected villages in the Mofussil. The statement of plague cases and deaths reported from stations at which railway medical inspections are carried out shows only 14 cases detected.

Dec. 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Health of Edinburgh for 1898.

THE mortality in Edinburgh for the past year was 5321, making the death-rate 17·99 per 1000. There were 1602 deaths of children under five years of age and 1485 of persons above sixty years. 256 were above eighty years and 25 above ninety years. Diseases of the chest accounted for 1720 deaths and zymotic diseases for 413, of which 9 were due to typhus fever, 27 to typhoid fever, 38 to diphtheria, 72 to scarlet fever, 134 to measles, 124 to whooping-cough, and 9 to erysipelas. The notifications for the year numbered 7368. These included 66 typhus fever, 244 typhoid fever, 269 diphtheria, 6 small-pox, 2388 scarlet fever, and 4395 measles. The number of cases treated in the City Hospital during the year was 2770. The deaths amounted to 5·30 per cent. of the cases admitted.

Health of Leith for 1898.

The number of deaths registered during the past year was 1334, making a death rate of 17 per 1000; 542 deaths were of children under five years of age and 350 of those under one year; 64 deaths were from infectious disease, this not, however, including the deaths in the fever hospital. Intimations under the Notification Act numbered 651, 354 being of scarlet fever, 112 erysipelas, 96 diphtheria, 67 typhoid fever, 8 puerperal fever, 7 small-pox, 5 membranous croup, and 2 continued fever.

Edinburgh Royal Infirmary.

The annual meeting of the court of contributors to the Edinburgh Royal Infirmary was held on Monday, Jan. 2nd. The annual report was submitted by the treasurer. From this report it appeared that the total number of patients treated during the year amounted to 9434, of whom 4277 were medical and 4499 surgical. The number of deaths was 699. There was a decrease of 194 on the total number of patients treated. The average daily number of patients was 698. The largest number on any one date was 749 and the lowest 600. The average time each patient was under treatment was twenty-seven days; 177 deaths took place within forty-eight hours after admission. Deducting these the percentage of deaths was 5·5. In the out-patient department 29,919 cases were attended to. The total ordinary receipts amounted to £30,383. The ordinary expenditure amounted to £41,885 being an increase of £800 over the previous year. The bulk of that increase was under the head of wages to tradesmen, nurses, &c. The annual cost of each patient was £60 0*s.* 1½*d.* The extraordinary receipts, consisting of legacies and donations of £100 and upwards, amounted to £80,965.

Jan. 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Children's Hospital, Temple-street, Dublin.

THE meeting in connexion with the Christmas festivities at the Children's Hospital on Dec. 28th which her Excellency the Countess Cadogan had kindly promised to honour by her patronage and presence was unavoidably postponed on account of the occurrence in the wards of the hospital of two cases which were suspected of being of an infectious nature.

Medical Appointments to the Dublin, Wicklow, and Wexford Railway Company.

The directors of the Dublin, Wicklow, and Wexford Railway Company have recently appointed Mr. James Raverty to be medical officer of the Bray district, in place of

Dr. Hamilton, deceased. Mr. P. A. McDermott, surgeon to St. Michael's Hospital, has been appointed medical attendant in the Kingstown district.

Belfast in 1899.

Owing to the area which, under a new Bill, was added to Belfast last year its size has increased from 6806 to 16,503 acres and its population from 300,000 to about 340,000. In old Belfast during the past year 3710 new buildings were erected, and 837 in the new area. The total ratable valuation of the old city is now £999,619, that of the added area is £114.280, which brings the total ratable valuation of the City of Belfast at the beginning of this year to £1,124,852.

Belfast Dispensary Districts.

At a meeting of the Belfast Dispensary Committee held on Jan. 2nd Dr. Whitaker (medical officer of health) suggested that there should be a general re-arrangement of the dispensary districts as this was, in his opinion, necessary owing to their growth in recent years. In Dublin, with a population of 245,000, he said, there were 15 dispensary medical officers, while in Belfast with 350,000 inhabitants they had only 12. The matter will probably have to be discussed again, as owing to the added area the work of the dispensary doctors in certain districts has been much increased.

Health of Belfast.

The Public Health Committee have been considering Dr. Lorrain Smith's special report and the whole matter will be dealt with at a special meeting of the city corporation. It appears from Dr. Whitaker's report presented to the Belfast council on Jan. 2nd that between Nov. 20th and Dec. 17th, 1898, 158 cases of typhoid fever, 71 of scarlet fever, 59 of simple continued fever, 29 of diphtheria, 27 of erysipelas, 7 of puerperal fever, and 5 of membranous croup were notified. There were 55 deaths from zymotic disease, 70 from phthisis, and 172 from diseases of the respiratory organs. The annual death-rate from all causes was 25·6, that for children under one year old 6·1, and that for those of sixty years and upwards 4·5 per 1000 of the inhabitants. The notifications of typhoid fever during the four weeks were less than half of those noted in the report presented on Dec. 1st. Scarlet fever is now rife in Belfast, but of a mild type. In the introductory address (at the first meeting of the council this year) the Lord Mayor (Sir James Henderson) stated that in 1897 the money spent in the Public Health Department was £17,746, while for 1899 the estimate is £29,475—a great and necessary increase.

The Meteorology of 1898.

During the year 1898 the total rainfall in the north of Ireland was 39·34 inches, the average for the previous fourteen years being 34·80 inches. Rain fell on 228 days. February was the wettest month (5·05 inches), September coming next (5 01 inches). The day on which there was the greatest rainfall (1·47 inches) was Nov. 23rd. The mean temperature was highest in August (59° F.) and it was lowest during February (40·6° F.). These statistics are from a record made at Coleraine.

The Battle of the Clubs at Cork.

The mayor of Cork and Mr. Long, chairman of the Queenstown Town Commissioners, have written jointly to the secretary of the Cork Medical Association stating that they would render assistance in settling the dispute between the medical men of the city and the clubs and adding that it would afford them pleasure to discuss the situation with a deputation appointed by the profession. The medical association, though aware that Mr. Long held the position of Grand Master of the Oddfellows of the South of Ireland and that he was therefore in a sense an interested party, decided that in all courtesy they should act on the suggestion conveyed to them, and accordingly Professor S. O'Sullivan and Dr. Edward Magner were appointed delegates. During the conference Mr. Long suggested the following terms: that the only remaining imported club medical officer should resign his clubs but be eligible for re-election; that instead of the original medical officers of the clubs being reinstated the club appointments should be open to competition; and that the imported medical man should be met in consultation by members of the profession in Cork. The medical delegates then stated that the proposal to throw the club appointments open to competition could not be entertained, as it would imply the desertion by the medical association of the club medical officers who had resigned those appointments in the interests of the profession at large. The delegates further added that under no possible combination of circumstances would the members of the Cork Medical Association consent to meet the imported medical man either professionally or socially. There is no doubt that one of the best strategic moves made by the profession in Cork has been the formation of the Cork Medical Benefit Association which although only in its infancy has had a successful career, as proved by the balance-sheet recently issued. One of the fundamental rules of this association is that no one having an income of over £100 a year shall be eligible for membership.

(FROM OUR OWN CORRESPONDENT.)

Hospital Physicians and Alcoholism.

AT the meeting of the Hospitals Medical Society held on Dec. 15th M. Legendre, alarmed by the ever-increasing amount of drunkenness, asked if it would not be possible to withstand this by means of meetings, insistence on the dangers of alcohol, and by what he considered an even better method, that of getting up for the instruction of patients lantern shows with exhibitions of anatomical preparations to show the dangers of alcohol. M. Legendre has had printed for the use of all his patients a litle leaflet setting forth in the clearest manner the evils which follow the use of alcohol. He gives one of these to every patient of his both on admission to hospital and when he is discharged. Besides this he has had them stuck up all over his wards and even in the lavatories as being quiet places where the patients will have leisure to read them with the object of bringing about a veritable obsession against alcohol. The text runs as follows: "Most of the diseases treated in the hospitals arise from alcoholic drinks—that is to say, they are either caused or aggravated by the abuse of alcohol. All alcoholic drinks are dangerous, and the most harmful are those which contain aromatics in addition to alcohol—as, for instance, *absinthe* and the so-called aperients called *amers.* Alcoholic drinks are more dangerous when taken on an empty stomach or between meals. A man necessarily becomes an alcoholic—i.e., slowly poisoned by alcohol—even if he never gets drunk, when every day he drinks alcohol in the form of liqueur or too much wine, more than one litre per diem. Alcohol is a poison the habitual use of which destroys more or less quickly, but none the less certainly, all the organs most necessary to life—the stomach, the liver, the kidneys, the blood-vessels, the heart, and the brain. Alcohol excites man but does not strengthen him. It is no substitute for food, but takes away the taste for it. Those who often drink alcohol or too much wine (more than one litre a day) are much more liable to illness, and when ill are much worse, for the disease is often complicated with fatal delirium. Alcohol is a frequent cause of consumption by its power of weakening the lungs. Every year we see patients who attend the hospitals for alcoholism come back some months later suffering from consumption. Fathers and mothers who drink often have children who are deformed or idiots or who die from fits."

The Broca Hospital.

On Dec. 21st the President of the Republic visited the Broca Hospital. He was received by the officials and heads of the various departments. The building, of which the very look is distressing, is in a most deplorable condition, being very deficient not only as regards its hygienic state, but even in regard to matters of ordinary decency. The wards are all very low and the paint and plaster are peeling off the walls. So the whole of the medical staff greeted M. Faure on his arrival with protests and complaints. With one voice the staff demanded that the building should be razed. Unfortunately the Broca Hospital is not the only one in this condition, for there are quite a dozen others in a like state. M. Faure, however, soon left this portion of the hospital and passed on to inspect the new Pascal block which is devoted to the department presided over by M. Pozzi. The official architect in his plans only carried out the ideas of M. Pozzi. The walls of the wards are covered with pictures and frescoes signed by such artists as Clairin, Lauzet, Girard, and Dubeuf, and M. Pozzi superintended the building day by day as it progressed. The building is entirely given up to the diseases of women. The building includes three distinct departments, but all these communicate freely with one another. There are rooms for consultations, the wards for the patients, a theatre, and operating rooms. The consultation rooms consist of a large waiting-hall from which a passage leads to a room for examination, an electrical department, and a room for massage. There are also a cloak-room for students, a private room for the surgeon, and rooms for douches, dressings, and speculum cases. 4 wards are allotted to hospital patients, 3 of which are gynæcological and 1 is reserved for syphilitic obstetric cases. There are also isolation wards with 1 or 2 beds and 1 special isolation ward for infectious cases. Altogether there are 66 beds. For lectures and operations there is a large theatre which also serves as an operating theatre for septic cases; but besides this there is another operating theatre, a sterilising room with the instrument cabinet, and an anæsthetising room. The floors throughout are tiled and not floored with planking, while the walls are covered with an unchangeable plaster. Heating is carried out by means of low-pressure steam apparatus and the electric light is supplied. The wards all look into the gardens. Every article of furniture is of iron, wood, and porcelain and will all take to pieces for sterilisation. The total cost was 440,000 francs, this being the amount originally allotted for expenses. 128,000 francs were allotted for the waiting-rooms, the remainder of the building and the theatre coming to 312,000 francs. Thus 66 beds were provided at a cost of about 4800 francs per bed—very little considering that in the most modern hospital, the Hôpital Boucicaut, the amount per bed will be 18,750 francs.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Iodoformogen.

OF the numerous chemical compounds manufactured commercially as substitutes for iodoform the greater part have proved to be of little value, and in spite of its unpleasant odour and its irritating action on the skin iodoform has for many years maintained its position as the most energetic of the antiseptic powders. Messrs. Knoll and Co., manufacturing chemists at Ludwigshafen, have, however, succeeded in producing a combination of iodoform with albumin which is in some respects superior to ordinary iodoform and is termed iodoformogen. It contains 10 per cent. of iodoform, has a yellow colour, may be sterilised at 105° C. (221° F.) without undergoing any alteration, is not soluble in water, and has hardly any smell. In addition to this it is more than three times lighter than iodoform and is lower in price. Dr. Wagner of the Stuttgart Hospital states in the *Munchener Medicinische Wochenschrift* that neither eczema nor toxic symptoms have occurred when it has been used. Eczema even disappeared when treated with iodoformogen. There is very little danger of it causing toxic symptoms as it contains only 10 per cent. of iodoform which owing to its combination with albumin is absorbed but slowly. The new preparation therefore seems to possess several distinct advantages.

Carbolic Acid Injections in Anthrax.

An interesting case of anthrax has been described in the *Munchener Medicinische Wochenschrift* by Dr. Strubell of the University Hospital of Jena. The patient was a tanner, forty-one years of age. Six days before coming under observation he observed on the tip of his nose a small blister which very soon became black. He continued at work till the day of his admission to hospital when he was seized with rigors and feverish symptoms. On his arrival at the hospital the lower part of his nose was extremely swollen, the skin was gangrenous, and there was marked infiltration of the surrounding parts. Typical bacilli of anthrax were present in the secretion of the nose. All the submaxillary glands were swollen and the spleen was enlarged. No bacilli, however, could be found in the blood and inoculations of mice and guinea-pigs with the blood had no result. Owing to the unfavourable state of the patient no operation was performed, but, as suggested by Russian observers, injections of a 3 per cent. solution of carbolic acid were made into the necrotic tissue of the nose, the surrounding tissues, and the infiltrated glands. Hot poultices at a temperature of from 50° to 55° C. (from 122° to 131° F.) were also applied night and day, being changed every ten minutes. Under this treatment the man's condition became better, so that within ten days a line of demarcation was formed between the tip of the nose and the surrounding tissues. The injections, however, were continued as the œdema had extended to the clavicles and there was therefore a possibility of general septicæmia supervening. After three weeks the infiltration at last stopped and the glands decreased, so that the injection was no longer necessary. The tip of the nose healed up with only very slight cicatrisations. The case is very interesting both on account of the unusual position of the lesion and also on account of the favourable issue. Although the prognosis was unfavourable conservative treatment succeeded in saving the patient. If an operation had been performed the result would certainly have been mutilation of the patient's face by resection of the nose, whilst under the injections healing took place without this disfigurement. The patient had more than 400 injections of 1 gramme of a 3 per cent. solution of carbolic acid without any toxic symptoms being produced. Dr. Strubell is of opinion that the hot poultices assisted in destroying the anthrax bacilli, for it is known that the latter are killed by a temperature of 42° C.

A Surgeon Charged with Neglect.

Some of the difficulties connected with surgical practice are very well illustrated by the following case quoted in the *Aerztliche Sachverstandige Zeitung.* An intoxicated working man was wounded in the neck in a scuffle and was brought to a surgeon who dressed the wounds and attended him for ten days in his (the patient's) residence. As the man's state became worse he was taken to a hospital where paresis of the right arm and motor aphasia were recognised. Seven days after admission trephining was performed and led to the discovery of a broken knife-blade which had perforated the dura mater and was fixed in the skull. Round the blade there was an abscess which increased in size after the removal of the foreign body and finally led to a fatal issue. The surgeon who had first attended the case was prosecuted for professional neglect and two other surgeons had to appear as experts before the court. They were asked by the prosecution (1) whether the defendant had sufficiently examined the wounds, and (2) whether if the blade had been at once removed from the skull the patient's life would have been saved. The answers to these questions were as follows—first, that there was no reason to believe that the surgeon had not sufficiently examined the wound, as he had not been informed that a knife had been used in the fight, and that even if he had introduced a probe into the wound there was little probability that the blade would have been detected as it was inside the skull; secondly, that even if the blade had been removed earlier the patient would probably have died, the knife not being free from pyogenic germs. The court agreed with the opinions of the expert witnesses and a verdict of "Not guilty" was returned

Jan 1st.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Public Hygiene.

THE year opens reassuringly for the "salus populi." I have had occasion to draw attention to the fact that zymotic and epidemic disease is never quite absent from Italy, mainly owing to the abject impecuniosity of the communes which are thus unable to afford the sanitary measures prescribed by sound hygiene. These communes are expected to carry out the provisions of the "Legge Sanitaria," but their predicament is simply that of "non possumus"—"our poverty but not our will consents." The Government, appealed to, like Hercules, to lift the sanitary machine out of the rut, pleads in its turn "non possumus" and protests that it has not at its disposal the funds needed for the prophylaxis of the whole kingdom. There are 8263 communes in Italy (mainland and islands) and the Ministry of the Interior has only 8000 lire Italiane set apart for prophylactic purposes—little over 6*d*. for each commune. In October last the Premier (General Pelloux) who is also Minister of the Interior promised to devise some means for palliating, if

William Thomson mentioned a district which measured a hundred square miles where there was but one dispensary medical officer and he was seventy years old. He could not retire, for the population was so poor that it was impossible to get any private practice. These are facts well known to the Irish Local Government Board, but that Board has never moved in the matter. The policy seems to be not to deal with any question unless absolutely forced to do so, and unfortunately the medical men in Ireland are lacking in cohesion; they do not work together as a body. Such efforts as have been made to unite the profession have so far failed and therefore there has not been a strong enough pressure brought to bear upon the Irish Local Government Board. While the medical men are content to submit to unjust treatment the Government will not go out of its way to redress the grievances of the dispensary medical officers.

The reform which many medical men themselves desire is that the dispensary medical officer should become a civil servant in the employ of the Government and not of the local authority. Candidates should be subjected to a special examination in regard to public health questions and as to their capacity to act as surgeons for the police, the prisons, the bridewells, the coastguards, &c. These functions added to the duties of dispensary medical officers would constitute a fair total income, making it worth while for high-class men to apply and to qualify for the special duties. As it is the local authorities only pay half the cost of the medicines and the salaries of the dispensary medical officers. The other half is paid by the central authority, therefore the Local Government Board of Ireland has as much right to nominate as the local authorities. If Ireland is to be civilised from the sanitary point of view it would be worth while for the Exchequer to pay more than half the cost so that the central authority could appoint men who would be competent and independent of local intrigues and pressure. This is more needed in regard to public health than in respect of the abuse by which medicine for others than the poor is obtained out of the rates. The Poor-law guardians and the dispensary committee-men are themselves often the chief offenders. They distribute both white and red medical relief tickets to their well-to-do customers and to their own families and otherwise commit abuses. They often set sanitary laws at defiance and have sometimes even been paid for their votes in the election of a dispensary medical officer. Under these circumstances these petty local bodies should be deprived of the power of nominating and tyrannising over the dispensary medical officers. They have given sufficient proof of the improper use which they make of such powers. For instance, according to the Act a medical officer should receive a guinea for attending a court in regard to a prosecution or to obtain a magistrate's order for compulsory burial, &c. But now it will be seen on referring to advertisements that the local authorities require applicants to contract themselves out of these advantages. Thus, for instance, the Rathdrum Union, Aughrim Dispensary district, recently advertised for a medical officer and the advertisement stated that the salary would be "£120 a year as medical officer and £15 a year as medical officer of health, such salaries to be taken to include remuneration for all services rendered under the Labourers Act and Sanitary Act as well as the Medical Charities Act, and the payment of a substitute when the doctor is absent owing to other cause than ill-health caught in the discharge of his duties." Again, the Sligo Union advertised for a medical officer for the Cliffoney Dispensary district. The salary was £100 and £20 more as medical officer of health, together with the usual vaccination and registration fees. Then comes this clause in the advertisement: "The person appointed must attend and give evidence in all sanitary prosecutions instituted by the sanitary authorities without any additional remuneration." It need scarcely be explained that these conditions will tend to reduce the number of prosecutions. A medical officer of health who only receives £20 a year cannot be expected to spend many days in law courts. But if he received an extra guinea for each case there might be some chance of prosecutions being instituted. As explained on a previous occasion the local authorities are, in the main, desirous of preventing any sanitary reform. The advertisements quoted above are evidence of the little concern felt in this respect and are in direct opposition to the spirit of sanitary legislation since they call upon the candidates to contract themselves out of the Sanitary Act. The Legislature, to encourage the prosecution of persons who offended against the laws of health, stipulated that the medical officer who gave evidence, &c., should receive a fee of a guinea. But the Sligo Board of Guardians sets itself above the Imperial Parliament and Government. It says that the medical officer shall not receive these guinea fees and by such an act it seems anxious to discourage instead of encourage prosecutions under the sanitary and other laws enacted for the benefit of the public health. Such advertisements should awaken the attention of the Government for they certainly suggest a desire to avoid applying the laws of the land. But they also indicate that there is good reason for not trusting these petty local bodies with the appointment of such important functionaries as the medical officers of health and the dispensary medical officers.

Then, again, in most other occupations the salary increases, but this is not the case with the dispensary medical officers and no difference is made between junior and senior officers. Thus a dispensary medical officer for a Dublin district told me that he was appointed thirty-five years ago and yet he receives to-day identically the same salary as he did on the first year of his appointment. Indeed he is, if anything, poorer, for money is now cheaper than it was when first he came into office. If, however, the appointments were in the hands of the central authority young men could be sent at first to the less important districts and as they gained in experience they might be promoted to more important and better paid districts. Thus a spirit of emulation would be engendered and there might at last be reasonable hope of seeing the public health laws applied with some show of vigour. Then when there were cases of abuse the dispensary medical officer would not depend on the local authority for redress. Even in Dublin tickets for dispensary medical attendance can be obtained from publicans or their potboys. One medical officer told me that he had to attend the family of a man who was earning £5 a week. Well paid workmen who are able to keep greyhounds for racing purposes also rank among his dispensary patients. It was of no use protesting—these people did not care. They would not even join a benefit society and pay a penny per week for medical aid. The relieving officers also gave tickets and seemed to think that they could not refuse them. Yet theoretically the person who gives a ticket for dispensary medical attendance is supposed to make an inquiry and to assure himself that the patient cannot afford to pay a practitioner's fee or to join a provident dispensary or benefit society. In view of all these facts it is evident that the system of dispensary medical aid is grossly abused, that it works most unsatisfactorily, and that sweeping reforms are urgently needed. The Irish Medical Association has brought this matter forward on several occasions, and though these efforts have met with but little success they must be continued and with even more energy.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Hospital Sunday Fund.

A MEETING of the committee of the Hospital Sunday Fund was held on Jan. 5th under the presidency of the Lord Mayor (Alderman Beale). The report showed that there was an increase in the total number of places of worship contributing, being 280 as compared with 254 in 1896, when, as now, the collections were given to the General Hospital. The gross receipts for this hospital in 1896 amounted to £4422 1*s.* 10*d.* and this year to £5245 15*s.* 8*d.* The Lord Mayor expressed the hope that the movement might be placed on a basis which would appeal in a broader spirit to the whole of the people and contrasted it with the Hospital Saturday movement. Still, it was satisfactory to know that the number of life governors and annual subscribers had been increased. It was pointed out that the expenditure of the General Hospital for the year ending Dec. 31st was £23,870, and towards that sum the committee had received £17,993, thus leaving a deficiency of £5877. They had received that day £4800, but they could only apply one-third of that sum toward the expenditure of the past year, still leaving a deficit.

Poisoning by Hyssop.

A singular case lately formed the subject of a coroner's inquiry where a pregnant woman made an infusion of a pennyworth of hyssop after taking which she died. She was stated to have been in bad health and the subject of Bright's disease. It is generally believed that the plants of the order to which this belongs—the Labiatæ—have no deleterious qualities, being carminatives and antispasmodics. However this may be as a rule, the medical witness at the inquest expressed his belief that the hyssop was the cause of the patient's death and the jury adopted his opinion, returning a verdict accordingly.

Electric Light at the Queen's Hospital.

The out-patient hall of the Queen's Hospital had the electric light service inaugurated on Jan. 6th. An installation of 350 sixteen-candle power incandescent lights was provided and pronounced a great success. In addition, all the medical and surgical officers' rooms, the theatre, the chapel, and the administrative departments are fitted with the same kind of light.

Adulteration of Gin.

At a local police-court on Jan. 3rd a publican was summoned for selling gin two degrees under the proof allowed by the law. The public analyst for Warwick said that he was unable to give the exact percentages of water and alcohol with the quantity of added water. The report of the analyst for the county of Worcester showed that the gin was 33·45 under proof and was therefore over the maximum standard of proof allowed by law. The defence submitted that the certificate should have given the percentages of water and spirit and it was therefore contended that there was no case as the certificate did not comply with that requirement. The case was dismissed.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Purification of Gas.

THOUGH gas is so great a convenience that even now with electric lighting on all sides the civilised world would be the worse for its extinction it must also be said that its impurities render it a great nuisance. In Manchester the large proportion of sulphur in the gas has for a long time been an annoyance and a reproach and it seems as if there were a prospect of its being still further increased. A question was asked at the last meeting of the city council as to what steps, if any, were being taken to reduce the abnormally high proportion of sulphur in the gas delivered and an ingenuous alderman said that there was no danger of the matter being overlooked. "It had had the serious attention of the gas committee ever since he had been a member." However serious the attention may have been it cannot have been serious enough for it has not removed the sulphur. And then another alderman, the chairman of the gas committee, rose up in his place and said that after much inquiry they had adopted a different process of carbonisation of coal—"the regenerator process"—which had been extremely satisfactory from an economical point of view, for they got 500 cubic feet more of gas per ton of coal carbonised. "But unfortunately it brought in its train a very considerable increase of sulphur," and as according to the scientific authorities "there was only one mode of purifying the gas from sulphur, and that was by lime, they would have to adopt the lime process." He thought they would be able to get a market for the lime and "that the Ship Canal would be of use in this respect." It is to be hoped that it will not be used to poison the fish at the mouth of the Mersey. It is a pity that the chemists who are great at the production of sulphuretted hydrogen cannot find some less cumbrous method of dealing with it.

Northwich and its late Medical Officer of Health.

An occurrence took place at Northwich recently which emphasises the desirability in the interests of justice and fairplay and also of the public weal of delivering medical officers of health from having their tenure of office subject to the caprice or self-interest of local cliques. It is reported in the *Manchester Courier* of Jan. 7th that "a heated discussion took place at the meeting of the Northwich Rural Council yesterday with reference to the discharge of Mr. Garstang, who for three years had occupied the position of medical officer of health of the district." The Local Government Board having "been asked to sanction the appointment of Mr. Gough wrote for the observations of the authority upon a letter received from Mr. Garstang, in which he said he feared his future prospects might be damaged unless some explanation of the council's last action was afforded." The clerk submitted the draft of a letter saying that there had not been the slightest intention of casting any reflection upon Mr. Garstang. After a warm debate, during which it was urged by several members "that the only reason that could be adduced for the discharge of Mr. Garstang was that he had done his duty too honestly and fearlessly," it was decided that no reasons should be given—which it is quite easy to understand as there seems to have been none to give—"and the simple form of reply was accepted by 14 votes to 8." In far too many places the medical officership of health is robbed of all its value as a safeguard of the public health from its being held at the mercy of those who may consider that a regard for their own supposed interests is a higher, or at all events a stronger, motive than regard for the life or health of their neighbours. It may be hoped that they are not always in the proportion of 14 to 8 over the conscientious members of the rural councils and that sometimes ignorance may be the mainspring of their actions, but however that may be the too frequent result is that if he does his duty the medical officer of health soon receives notice to quit.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Opening of the New Wing of the Longmore Hospital for Incurables, Edinburgh.

ON the afternoon of Jan. 5th Her Grace the Duchess of Buccleuch performed the ceremony of opening the new wing of the Longmore Hospital. The Marquis of Lothian presided at the ceremony and in opening the proceedings he gave a short outline of the progress of the institution. The central part of the hospital, which was the first part erected, was opened in 1880. The present east wing was opened in 1891 by the Duke of York and Princess May, at which time a children's ward was established. The directors had been enabled to meet the expense of the present extension by the liberal bequest of Mr. Peter Waddell. The work of the institution had been begun in 1875 with 22 patients; now they had accommodation for 150 patients. Mr. J. A. Wenley, chairman of the house committee, referred to the history of the hospital and to the various legacies and donations which had enabled the directors to carry forward the work of the institution. In addition to the new wing they had a new laundry, a new kitchen, a new chapel and mortuary, and the whole building was now lighted by electric light. The cost of all these improvements had been about £25,000. The working expenditure of the hospital had largely to be met from annual subscriptions and as the amount necessary for keeping it up would now be increased they would have to rely on the generosity of the public to meet this increase. To carry on the new wing they would need about £600 annually in addition to their former revenue. The Duchess of Buccleuch, after speaking for a few minutes, declared the new wing open. Mr. D. M. Westland, on proposing a vote of thanks to the Duchess, presented her with a small key made of Scottish gold. The new wing, two storeys in height with a basement, is attached to the main building by a wide corridor of iron and glass. The ground floor is set apart for phthisical patients, while the upper floor is intended for the reception of cases of cancer. The kitchen premises have been reconstructed and additional rooms have been provided above the kitchen for the nursing staff. The new washing houses and laundries are in a separate building and the drainage has been entirely remodelled, iron pipes having been substituted for fire-clay ones. The main drains and connexions are placed in subways so as to be easy of access, and the drainage subway has been utilised to give access to the mortuary buildings which are placed at the Causewayside entrance to the hospital grounds. They consist of a post-mortem room and mortuary lined to the ceiling with glazed tiles, a chapel, and a specimen room, with a dark room for photographic purposes attached.

The University of Edinburgh: Statistics for the Year 1898.

The total number of matriculated students during the past year was 2813. Of this number 1387 (including 6 women) were enrolled in the Faculty of Medicine. The number of women attending extra-academical lectures with a view to graduation in the University was 89. Of the students of medicine in the University 584, or over 42 per cent., belonged to Scotland; 374, or 27 per cent., came from England or Wales; 94 from Ireland, 60 from India, 231 from British colonies, and 44 from foreign countries. During 1898 the following degrees in medicine had been conferred: M.B., C.M., 60 (including 2 women); M.B., Ch.B., 138 (including 6 women); M.D., 73 (including 1 woman). There had been 29 recipients of the honorary degree of LL.D. during the year, this large number being accounted for by the visit to Edinburgh of the British Medical Association. Among the honorary graduates was Lord Kitchener of Khartoum who had received the degree at a special graduation ceremonial held in November. The total annual value of the university fellowships, scholarships, bursaries, and prizes now amounted to £17,790. Of this £3000 were distributed in the Faculty of Medicine. In addition to the above a sum of upwards of £600, the income of the Earl of Moray Endowment Fund, was annually available for original research.

Extension of the Montrose Asylum.

At the monthly meeting of the managers of the Sunnyside Royal Lunatic Asylum in Montrose on Jan. 3rd the question of extension of the asylum again came up for consideration. Under the new regulations as to the number of cubic feet of air-space for each patient the asylum was at present in the condition of having 124 patients too many. In the report of Dr. Fraser, Commissioner in Lunacy, attention was drawn to the overcrowded state of the asylum. The asylum house committee recommended that in order to reduce the present overcrowding two houses should be erected on the high ground behind the present asylum, each to accommodate from 30 to 50 patients. After discussion the meeting agreed to the recommendation of the committee and instructed them to carry out the "forward policy" with all speed.

The University of Aberdeen.

The Aberdeen Town Council has disapproved of the plans for the "restoration" of old Greyfriars Church, the majority being in favour of demolishing the structure and erecting a new church on another site, as contemplated by the Act of Parliament authorising the extension of the University buildings at Marischal College. Owing to this resolution steps are being taken to put the University in possession of funds to carry on the original extension scheme, it being feared that Mr. C. W. Mitchell, Jesmond Towers, Newcastle-on-Tyne, who offered (at first anonymously) a contribution of £10,000 on the condition of old Greyfriars Church, which is so far a pre-Reformation building, being retained in a "restored" form, may now withdraw the proferred subscription.—The medical and other classes resumed work this week after the Christmas vacation.

Aberdeen Hospital Sunday.

New Year's day was Hospital Sunday in Aberdeen, though several of the church collections were either not made or not completed till Jan. 8th. The collections (from 62 churches) on Jan. 1st alone amounted to £1155 and altogether the Royal Infirmary will receive several hundreds of pounds more than it received last year.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Prevention of Tuberculosis in Dublin.

A LONG letter has recently appeared in the columns of the *Irish Times* from the pen of Professor Antony Roche, lecturer on public health at the Medical School of the Catholic University, referring to the meeting of the National Association for the Prevention of Consumption lately held under the presidency of the Prince of Wales and suggesting that the occasion should have a special interest for the inhabitants of Dublin—a city in which the mortality from tuberculous disease is relatively high, being much higher than that which is shown to exist, for instance, in London. The death-rate it appears from this class of disease has, moreover, continued at a high level in Dublin notwithstanding that it has slowly declined in many other cities and in the country at large. Mr. Roche therefore considers that the metropolis of Ireland is especially in need of remedial measures as regards that department of public health. The isolation of cases of phthisis is a matter of very considerable difficulty and expense, and if we include under that term all the surgical as well as the medical manifestations of tuberculosis it seems absurd to hope that separation or isolation can prove a really practical and effective measure for years to come. The reason of this is to be found of course in the fact that although the disease is distinctly capable of propagation and properly ranks as an infectious disorder it differs from all the other affections so classed in this country in its chronicity, and in the fact that subjects of tuberculous disease are often moving about and attending to their business for years before they finally become invalided. Mr. Roche suggests some measures of a practical character which might be easily and without much expense adopted in Dublin—amongst others the disinfection of houses in which tuberculous patients have died, the inspection of the city meat-supply, the exclusion of dairy-yards from within the city boundary, the treatment of all milch cows with tuberculin in order to ascertain whether they are entirely free from tuberculous disease, &c.

The Dental Hospital of Ireland.

A general meeting of the governors and subscribers of the Dental Hospital of Ireland was held in the new building in Lincoln-place on Jan. 9th to approve of the memorandum and articles of association for the purpose of incorporating the institution under the Companies Acts, 1867, and to nominate members of the Executive Committee to subscribe the memorandum and articles for the purpose of incorporation. Mr. James J. Pollock, J.P., filled the chair and received the names of many influential persons nominated to subscribe the memorandum and articles of association. It appears that when the institution was in York-street it was only a voluntary society without any incorporation and after removal to the new building in Lincoln-place it remained so. The governors now wish to look for some constitutive and legal status so that they may be no longer merely a voluntarily formed body and in order to bring this about they are taking measures to register the hospital as a private company under the Acts of 1867. The effect of this would be that the institution could not be worked for profit but for the public benefit. A resolution approving of the steps taken was passed, the object of the incorporation being to take over the existing hospital as it stands and to carry on there in future the business of the Incorporated Dental Hospital of Ireland.

Prosecution under the Public Health Act.

An important case came on at the Belfast Police Courts on Jan. 3rd when the corporation summoned a woman for permitting a new building to be occupied as a dwelling-house before the house drainage had been completed and the house approved of by the city surveyor as fit for habitation. It would appear that the defendant had passed plans with the corporation for the erection of three houses, these plans showing the drains connected with the sewer. No drains had been made and notwithstanding the warnings of the corporation the woman and her family had gone into occupation of one of the houses. The magistrates entered a nominal penalty of 40s. as a company had been bound under agreement with the corporation to make the sewer and the defendant had purchased the ground believing this agreement existed. The company had, however, changed hands and the new owners refused to carry out the covenant.

The Ulster Medical Society.

The monthly meeting of the Ulster Medical Society was held on Jan. 6th in the Museum, Belfast, when Dr. Cecil Shaw read a paper on Post-nasal Growths, giving an account of the etiology, diagnosis, and treatment of these adenoid tumours. Dr. E. C. Bigger and Dr. Robert Campbell read notes of a case of Operation for Perforated Typhoid Ulcer. The patient who was a man was in the Union Hospital under Dr. Bigger and symptoms of perforation occurred about the third week of the disease. The abdomen was opened and a perforated ulcer was discovered in the ilium about

2 ft. from the cæcum through which fæcal matter was passing into the peritoneal cavity. It was carefully closed, but the patient after making a rally died on the fourth day after operation from exhaustion. A post-mortem examination showed that the opening was closed and that the intestine was watertight. An interesting discussion followed the reading of these communications in which Dr. Walton Browne, Professor Sinclair, Dr. A. B. Mitchell, Professor Byers, Dr. Allan, Dr. Killen, Dr. John Campbell, and the President took part. Dr. John Campbell read notes of a case of Removal of Cancer of the Rectum by Kraske's Method and a case of Nephrorrhaphy for Moveable Kidney.

The Public Health Committee, Belfast.

At a meeting of the Public Health Committee of the Belfast Corporation held on Jan. 5th "attention was drawn to the damaging effect the exaggerated and in many cases unfounded statements made in journals of some standing regarding the unsanitary condition of some parts of the city would have if these statements were not contradicted, but being of a general and irresponsible character it was hard to contradict these unless specific information was given by the papers making the charges and the medical superintendent officer was instructed to apply to the editors for this."

The Belfast and District Lunatic Asylum.

At the monthly meeting held on Jan. 9th it was reported that 931 patients were on the asylum register. A statement by the chairman (Professor Cuming, M.D. R.U.I.) showed how curiously the Board of Control in Dublin manage matters. It appeared that a committee of the asylum governors had an interview with the Finance Committee of the Belfast Corporation with reference to the fees of the architect for work done in connexion with the Purdysburn Asylum. At that interview they found, to their astonishment, that while they (the governors) had sanctioned a preliminary payment of £2000 only the Board of Control in Dublin had asked the Finance Committee for £4000. In reply to the corporation the governors could give no explanation of this matter as they knew nothing of it. However, they decided to write to the Board of Control and they then, in reply, wrote withdrawing their request for £4000 and said what they wanted was only £2000 which the governors had voted and £700 for quantities. The governors had decided upon the erection of two blocks and part of an administrative building at £65,000 and it was architect's fees on these the governors sanctioned. The whole matter will probably be left in the hands of the new board which will soon come into being.

County Antrim Asylum.

At a meeting of the governors of the County Antrim Asylum held on Jan. 9th a communication was received from Sir David Harrel expressing the dissatisfaction of the Board of Control with the new asylum works and asking the governors to appoint a committee to meet a committee of the Board of Control with the engineers at the works. A committee was accordingly appointed.

Jan. 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Waste in the Assistance Publique.—Abuse of Maternity Charities.

THE mortality among women confined in the Paris hospitals was some twenty years ago very high. Thanks to Tarnier whose memory must ever be held in respect puerperal fever has now become exceedingly rare in lying-in hospitals, for the young mothers are surrounded with every possible antiseptic care; and the theories of Pasteur applied to obstetrics by Tarnier and his pupils have saved thousands of lives. But the enormous progress made in this line of practice and the excessive care which is taken have had the result of causing the hospitals to be invaded by a very different class to that for which they were originally intended, and the proportion of midwifery cases undertaken at the expense of the Assistance Publique has increased to an alarming extent. Three-fifths of all the births in Paris are paid for by this association. It is unjust, if not dangerous, to draw upon the income of the Assistance Publique for the benefit of the well-to-do classes. Professor Pierre Budin, a well-known authority in the matter, recently gave a lecture at the Maternité Hospital in which he brought forward the following figures. In 1877 the number of lying-in cases attended by the registered midwives of the Assistance Publique was 3486; in 1896 it had increased to 5876. It was considered that the registered midwife would gradually disappear as the number of hospital beds increased, but this hope has not been realised. The Assistance Publique exercises supervision, not only over its own registered midwives, but also over those attached to the various charitable organisations who attend lying-in women at their own homes, because they either do not wish or are unable to go into hospital to be confined. In 1877 there were 10,680 such cases; in 1896 the figures had risen to 12,025. On adding the totals for 1877 and 1878 it is found that 19,300 cases were attended by the Assistance Publique, while in 1896 the figures rose to 31,987. The numbers have grown very rapidly, especially as regards hospital cases—namely, 14,096. As there are from 50,000 to 55,000 births per annum in Paris it will be easily seen that three-fifths of these happen under the care of the Assistance Publique. The causes of this increase are many and various. First of all the number of maternity beds has doubled. Secondly, patients no longer shun the hospitals as formerly, for knowing the results obtained by antisepsis and good hygiene women flock to the hospitals to obtain that care which they cannot obtain in their own homes. Thirdly, facilities for getting about have largely increased owing to railways and tramcars so that easy access to the hospitals is now at the service, not merely of Parisians, but also of those dwelling in the rest of the Department of the Seine and even of those from more distant departments.

The Brain of Vacher.

Vacher, the well-known vagabond and the author of 18 murders, who had already gained a niche in popular legend under the name of the "shepherd slaughterer," has been guillotined. During the eighteen months of his imprisonment he was the object both before and after his condemnation of numberless medico-legal inquiries and his case gave rise to much scientific controversy. In the opinion of many psychologists he was quite irresponsible. As a fact he always was an odd character, very violent and erotic to the point of disease (*maladivement*). He had been in an asylum, from which, however, after a stay of some months he was discharged as cured Owing to some love trouble he shot himself twice in the head with a revolver. One of the bullets could not be extracted and was the cause of a marked facial paralysis with occasional attacks of acute neuralgia. After leaving the asylum Vacher began his life of wandering, in the course of which he committed 18 murders, in all of which, with the exception of one, the victim was a young boy or girl. They were accompanied with violation or mutilation of the body, evisceration, and removal of the genital organs or the breasts. Vacher declared that the acts were committed under an irresistible impulse and that after their committal he felt the greatest possible relief. Dr. Lacassagne, Professor of Forensic Medicine at the faculty of Lyons, assisted by Dr. Bebatel and other noted psychologists who were deputed to examine Vacher, came to the conclusion after a long and careful examination that he was responsible. Dr. Lacassagne considers that Vacher was simply a clever impostor who was well acquainted with the symptoms of ordinary madness owing to his stay in the asylum and who from the very commencement of his murderous career had counted on the immunity he would receive by pleading madness. The methodical way in which he set about his crimes, the precautions he employed to overcome his victim at once, to cut the throat on the one side while he stood on the other so as to avoid the spout of blood from the carotids, the skill displayed in the hiding of the body and the way in which he removed himself from the danger zone by travelling the most extraordinary distances, sometimes as much as sixty kilometres across country in one night,—all these considerations forced the experts to conclude that Vacher was only shamming. His attitude on trial when he offered the most ingenious defences confirmed this opinion and the jury unanimously condemned him to death. This verdict, however, did not put an end to the scientific discussions on the matter. Dr. Madeuf, the aural surgeon, held that the unextracted bullet which was lodged in the petrous portion of the temporal bone was possibly the cause of and mortuary lined to the ceiling with glazed tiles, a chapel, and a specimen room, with a dark room for photographic purposes attached.

The University of Edinburgh: Statistics for the Year 1898.

The total number of matriculated students during the past year was 2813. Of this number 1387 (including 6 women) were enrolled in the Faculty of Medicine. Aberdeen Hospital Sunday.

New Year's day was Hospital Sunday in Aberdeen, though several of the church collections were either not made or not completed till Jan. 8th. The collections (from 62 churches) on Jan. 1st alone amounted to £1155 and altogether the Royal Infirmary will receive several hundreds of pounds more than it received last year.

Jan 10th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Prevention of Tuberculosis in Dublin.

A LONG letter has recently appeared in the columns of the *Irish Times* from the pen of Professor Antony Roche, lecturer on public health at the Medical School of the Catholic University, referring to the meeting of the National Association for the Prevention of Consumption lately held under the presidency of the Prince of Wales and suggesting that the occasion should have a special interest for the inhabitants of Dublin—a city in which the mortality from tuberculous disease is relatively high, being much higher than that which is shown to exist, for instance, in London. The death-rate it appears from this class of disease has, moreover, continued at a high level in Dublin notwithstanding that it has slowly declined in many other cities and in the country at large. Mr. Roche therefore considers that the metropolis of Ireland is especially in need of remedial measures as regards that department of public health. The isolation of cases of phthisis is a matter of very considerable difficulty and expense, and if we include under that term all the surgical as well as the medical manifestations of tuberculosis it seems absurd to hope that separation or isolation can prove a really practical and effective measure for years to come. The reason of this is to be found, of course in the fact that although the disease is distinctly capable of propagation and properly ranks as an infectious disorder it differs from all the other affections so classed in this country in its chronicity. and in the fact that subjects of tuberculous disease are often moving about and attending to their business for years before they finally become invalided. Mr. Roche suggests some measures of a practical character which might be easily and without much expense adopted in Dublin—amongst others the disinfection of houses in which tuberculous patients have died, the inspection of the city meat-supply, the exclusion of dairy-yards from within the city boundary, the treatment of all milch cows with tuberculin in order to ascertain whether they are entirely free from tuberculous disease, &c.

The Dental Hospital of Ireland.

A general meeting of the governors and subscribers of the Dental Hospital of Ireland was held in the new building in Lincoln-place on Jan. 9th to approve of the memorandum and articles of association for the purpose of incorporating the institution under the Companies Acts, 1867, and to nominate members of the Executive Committee to subscribe the memorandum and articles for the purpose of incorporation. Mr. James J. Pollock, J.P., filled the chair and received the names of many influential persons nominated to subscribe the memorandum and articles of association. It appears that when the institution was in York-street it was only a voluntary society without any incorporation and after removal to the new building in Lincoln-place it remained so. The governors now wish to look for some constitutive and legal status so that they may be no longer merely a voluntarily formed body and in order to bring this about they are taking measures to register the hospital as a private company under the Acts of 1867. The effect of this would be that the institution could not be worked for profit but for the public benefit. A resolution approving of the steps taken was passed, the object of the incorporation being to take over the existing hospital as it stands and to carry on there in future the business of the Incorporated Dental Hospital of Ireland.

Prosecution under the Public Health Act.

An important case came on at the Belfast Police Courts on Jan. 3rd when the corporation summoned a woman for permitting a new building to be occupied as a dwelling-house before the house drainage had been completed and the house approved of by the city surveyor as fit for habitation. It would appear that the defendant had passed plans with the corporation for the erection of three houses, these plans showing the drains connected with the sewer. No drains had been made and notwithstanding the warnings of the corporation the woman and her family had gone into occupation of one of the houses. The magistrates entered a nominal penalty of 40*s.* as a company had been bound under agreement with the corporation to make the sewer and the defendant had purchased the ground believing this agreement existed. The company had, however, changed hands and the new owners refused to carry out the covenant.

The Ulster Medical Society.

The monthly meeting of the Ulster Medical Society was held on Jan. 6th in the Museum, Belfast, when Dr. Cecil Shaw read a paper on Post-nasal Growths, giving an account of the etiology, diagnosis, and treatment of these adenoid tumours. Dr. E. C. Bigger and Dr. Robert Campbell read notes of a case of Operation for Perforated Typhoid Ulcer. The patient who was a man was in the Union Hospital under Dr. Bigger and symptoms of perforation occurred about the third week of the disease. The abdomen was opened and a perforated ulcer was discovered in the ilium about

2 ft. from the cæcum through which fæcal matter was passing into the peritoneal cavity. It was carefully closed, but the patient after making a rally died on the fourth day after operation from exhaustion. A post-mortem examination showed that the opening was closed and that the intestine was watertight. An interesting discussion followed the reading of these communications in which Dr. Walton Browne, Professor Sinclair, Dr. A. B. Mitchell, Professor Byers, Dr. Allan, Dr. Killen, Dr. John Campbell, and the President took part. Dr. John Campbell read notes of a case of Removal of Cancer of the Rectum by Kraske's Method and a case of Nephrorrhaphy for Moveable Kidney.

The Public Health Committee, Belfast.

At a meeting of the Public Health Committee of the Belfast Corporation held on Jan. 5th "attention was drawn to the damaging effect the exaggerated and in many cases unfounded statements made in journals of some standing regarding the unsanitary condition of some parts of the city would have if these statements were not contradicted, but being of a general and irresponsible character it was hard to contradict these unless specific information was given by the papers making the charges and the medical superintendent officer was instructed to apply to the editors for this."

The Belfast and District Lunatic Asylum.

At the monthly meeting held on Jan. 9th it was reported that 981 patients were on the asylum register. A statement by the chairman (Professor Cuming, M.D. R.U.I.) showed how curiously the Board of Control in Dublin manage matters. It appeared that a committee of the asylum governors had an interview with the Finance Committee of the Belfast Corporation with reference to the fees of the architect for work done in connexion with the Purdysburn Asylum. At that interview they found, to their astonishment, that while they (the governors) had sanctioned a preliminary payment of £2000 only the Board of Control in Dublin had asked the Finance Committee for £4000. In reply to the corporation the governors could give no explanation of this matter as they knew nothing of it. However, they decided to write to the Board of Control and they then, in reply, wrote withdrawing their request for £4000 and said what they wanted was only £2000 which the governors had voted and £700 for quantities. The governors had decided upon the erection of two blocks and part of an administrative building at £65,000 and it was architect's fees on these the governors sanctioned. The whole matter will probably be left in the hands of the new board which will soon come into being.

County Antrim Asylum.

At a meeting of the governors of the County Antrim Asylum held on Jan. 9th a communication was received from Sir David Harrel expressing the dissatisfaction of the Board of Control with the new asylum works and asking the governors to appoint a committee to meet a committee of the Board of Control with the engineers at the works. A committee was accordingly appointed.

Jan. 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Waste in the Assistance Publique.—Abuse of Maternity Charities.

THE mortality among women confined in the Paris hospitals was some twenty years ago very high. Thanks to Tarnier whose memory must ever be held in respect puerperal fever has now become exceedingly rare in lying-in hospitals, for the young mothers are surrounded with every possible antiseptic care; and the theories of Pasteur applied to obstetrics by Tarnier and his pupils have saved thousands of lives. But the enormous progress made in this line of practice and the excessive care which is taken have had the result of causing the hospitals to be invaded by a very different class to that for which they were originally intended, and the proportion of midwifery cases undertaken at the expense of the Assistance Publique has increased to an alarming extent. Three-fifths of all the births in Paris are paid for by this association. It is unjust, if not dangerous, to draw upon the income of the Assistance Publique for the benefit of the well-to-do classes. Professor Pierre Budin, a well-known authority in the matter, recently gave a lecture at the Maternité Hospital in which he brought forward the following figures. In 1877 the number of lying-in cases attended by the registered midwives of the Assistance Publique was 3486; in 1896 it had increased to 5876. It was considered that the registered midwife would gradually disappear as the number of hospital beds increased, but this hope has not been realised. The Assistance Publique exercises supervision, not only over its own registered midwives, but also over those attached to the various charitable organisations who attend lying-in women at their own homes, because they either do not wish or are unable to go into hospital to be confined. In 1877 there were 10,680 such cases; in 1896 the figures had risen to 12,025. On adding the totals for 1877 and 1878 it is found that 19,300 cases were attended by the Assistance Publique, while in 1896 the figures rose to 31,987. The numbers have grown very rapidly, especially as regards hospital cases—namely, 14,096. As there are from 50,000 to 55,000 births per annum in Paris it will be easily seen that three-fifths of these happen under the care of the Assistance Publique. The causes of this increase are many and various. First of all the number of maternity beds has doubled. Secondly, patients no longer shun the hospitals as formerly, for knowing the results obtained by antisepsis and good hygiene women flock to the hospitals to obtain that care which they cannot obtain in their own homes. Thirdly, facilities for getting about have largely increased owing to railways and tramcars so that easy access to the hospitals is now at the service, not merely of Parisians, but also of those dwelling in the rest of the Department of the Seine and even of those from more distant departments.

The Brain of Vacher.

Vacher, the well-known vagabond and the author of 18 murders, who had already gained a niche in popular legend under the name of the "shepherd slaughterer," has been guillotined. During the eighteen months of his imprisonment he was the object both before and after his condemnation of numberless medico-legal inquiries and his case gave rise to much scientific controversy. In the opinion of many psychologists he was quite irresponsible. As a fact he always was an odd character, very violent and erotic to the point of disease (*maladivement*). He had been in an asylum, from which, however, after a stay of some months he was discharged as cured Owing to some love trouble he shot himself twice in the head with a revolver. One of the bullets could not be extracted and was the cause of a marked facial paralysis with occasional attacks of acute neuralgia. After leaving the asylum Vacher began his life of wandering, in the course of which he committed 18 murders, in all of which, with the exception of one, the victim was a young boy or girl. They were accompanied with violation or mutilation of the body, evisceration, and removal of the genital organs or the breasts. Vacher declared that the acts were committed under an irresistible impulse and that after their committal he felt the greatest possible relief. Dr. Lacassagne, Professor of Forensic Medicine at the faculty of Lyons, assisted by Dr. Bebatel and other noted psychologists who were deputed to examine Vacher, came to the conclusion after a long and careful examination that he was responsible. Dr. Lacassagne considers that Vacher was simply a clever impostor who was well acquainted with the symptoms of ordinary madness owing to his stay in the asylum and who from the very commencement of his murderous career had counted on the immunity he would receive by pleading madness. The methodical way in which he set about his crimes, the precautions he employed to overcome his victim at once, to cut the throat on the one side while he stood on the other so as to avoid the spout of blood from the carotids, the skill displayed in the hiding of the body and the way in which he removed himself from the danger zone by travelling the most extraordinary distances, sometimes as much as sixty kilometres across country in one night,—all these considerations forced the experts to conclude that Vacher was only shamming. His attitude on trial when he offered the most ingenious defences confirmed this opinion and the jury unanimously condemned him to death. This verdict, however, did not put an end to the scientific discussions on the matter. Dr. Madeuf, the aural surgeon, held that the unextracted bullet which was lodged in the petrous portion of the temporal bone was possibly the cause of the nation. It was accomplished through the intelligence and patriotism of all who served, from the Commander-in-chief to the private in the ranks. It also speaks volumes for the prompt, patriotic, and intelligent assistance of the people who furnished in so short a time the supplies necessary to prepare this great army for the field. The deaths in the army from May 1st to Oct. 1st, including the killed, those who died from wounds, and those who succumbed to disease, were 2910, the smallest death-rate recorded of any army in history—a remarkable fact when it is considered that over 50,000 of our troops, born and reared in a temperate climate, were campaigning in a tropical zone, subjected to heat and rain almost unprecedented.

The Work of the Life Savers.

The general superintendent of the Life-saving Service in his annual report says that at the close of the last fiscal year the establishment embraced 264 stations—192 on the Atlantic coast, 56 on the lakes, 15 on the Pacific, and one on the Falls of the Ohio at Louisville. The number of disasters to documented vessels within the field of operations of the service was 402 and there were on board 3113 persons, of whom 12 were lost; 663 shipwrecked persons received succour at the stations of the service. The number of vessels totally lost was 59. There were also 365 casualties to small craft, on board of which there were 874 persons, of whom 10 were lost; 56 other persons were rescued who had fallen from wharves, piers, &c., most of whom would have perished except for the aid of the life-saving crews. These crews saved and assisted to save 471 vessels in distress valued with their cargoes at $2,868,655, and rendered assistance of minor importance to 324 vessels besides in distress and also warned from danger by signals of patrolmen 226 vessels. The investigations made into the details of all shipwrecks involving loss of life and the conduct of the life-saving crews at these wrecks show that no life was lost through lack of faithful and intelligent effort on the part of life-saving men who on all occasions proved themselves equal to the requirements of duty. The number of disasters within the scope of the service was much larger than the number in any previous year. The loss of life, however, was only 22, against 53 in the preceding year when the number of disasters was much smaller and was less in proportion to the number of wrecks than ever before. The following is a general summary of the statistics of the service from the introduction of the present system in 1871 to the close of the fiscal year ended June 30th, 1898: number of persons involved, 81,245; number of lives lost, 845; number of persons succoured, 13,876.

The Marine Hospital Service.

With the close of the fiscal year 1898 the United States Marine Hospital Service completed the one hundredth year of its existence, the original Act for the Relief of Sick and Disabled Seamen having been passed by Congress on July 16th, 1798. At the present time the *personnel* of the service is as follows: Commissioned medical officers, 75, including the surgeon-general, 21 surgeons, 27 passed assistant surgeons, and 26 assistant surgeons. There are, in addition, 136 non-commissioned officers—viz., acting assistant surgeons, 98; sanitary inspectors, 4; and hospital stewards, 34. When all the stations have their full complement of attendants and quarantine employés there are in addition about 400 men employed in this branch of the Government. This number is of necessity much increased during epidemics. There are 21 hospitals owned and worked by the service and 11 quarantine stations; but in addition to these there are 88 localities in the United States where patients of the service receive dispensary and hospital treatment. During the fiscal year 1898 the total number of beneficiaries of the service treated at dispensaries and hospitals was 52,709, and of this number 11,914 were hospital patients. To assist in the prevention of the introduction of contagious diseases into the United States sanitary inspectors have been stationed at Habana, Santiago de Cuba, Rio de Janeiro, and at Yokohama. Two skilled bacteriologists of the Marine Hospital Service were especially detailed to investigate in Habana the cause of yellow fever. A laboratory was established and they continued their labours till obliged to withdraw on account of the war. They have now returned to Habana and are continuing the investigation and their preliminary report, published in the annual report of the service, indicates that the true cause of the disease has been found by Professor Sanarelli in the bacillus icteroides.

Dec. 18th, 1898.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Public Health of Sydney.

THE quarterly report of the medical adviser to the Sydney Board of Water-Supply and Sewerage showed that a slight increase had occurred in the death-rate owing to the epidemic of measles. In zymotic diseases the death-rate had risen from 1·6 per 1000 at the end of June to 5 per 1000 at the end of August, but fell in September to 1·5. The death-rate from respiratory disorders also had increased. More cases of diphtheria had occurred and the number of cases of typhoid fever was double that for the corresponding period last year. This may be partly accounted for by the fact that notification was not compulsory until this year. An analysis of the sanitary conditions existing in cases of typhoid fever is suggestive of the value of the sewerage system. In 33 out of the 68 cases no sewers were available and in 19 the houses were insanitary. In 14 cases the regulations were complied with, but 9 of the patients were school-children. The report emphasised the improvement in the public health which had followed the installation of the sewerage system and stated further that the men working in the sewers invariably enjoyed good health. The mean temperature during the quarter had been lower than the average and the temperature had also shown marked fluctuations, ranging from 40·4° F. in July to 89·8° in September. The sudden changes in the temperature are held responsible for an increase in the deaths from phthisis.

The Melbourne Hospital.

The annual expenditure of the Melbourne Hospital now amounts to £25,953. Three years ago it was £22,500. The receipts, on the other hand, have diminished from £25,700 in 1896 to £20,645. The increased expenditure affects all items except that for printing and is partly accounted for by the fact that the daily average of patients has increased from 271 in 1896 to 295 in the present year and by the great increase in the number of operations. The largest item of expenditure is for wages—£5912 paid to 179 employés. The sub-committee appointed to consider the best way of reducing the expenditure and increasing the income has presented a report. It is advised that the contract system be extended to every department, including the supply of bread and repairs to buildings. Waste is to be prevented by a system of fines on all employés found guilty of waste. The diets are to be more closely supervised by the medical superintendent. With a view of augmenting the income it is proposed to charge a registration fee to all patients, in- as well as out-door; visitors to patients are to be charged 6*d.* a ticket of admission; students are to pay annual fees in addition to the entrance fees; municipal bodies, country as well as urban, are to be asked to contribute to the funds; and the collecting staff is to be reorganised.—The present system of electing the honorary staff of the Melbourne Hospital by the subscribers to the institution has frequently been condemned. A public meeting was recently held to discuss the question. It was convened by the Charity Organisation Society and Professor G. E. Morris occupied the chair. He said that the present system was degrading to the noble profession of medicine. It wholly failed to secure the best men for the position and was quite out of date. He advocated the formation of an election committee consisting of 4 representatives appointed by the governor in council, 4 elected by the medical profession, 2 by the faculty of medicine of the Melbourne University, and 5 by the committee of the hospital. It was finally resolved that it was desirable that no annual subscriber to a metropolitan hospital should be permitted to exercise the right of voting at any election of the medical or surgical staff unless his or her name should have been on the list of subscribers for three years immediately preceding such election and that it was desirable to extend the term of service of the members of the staff from four years to seven.

Prince Alfred Hospital, Sydney.

It has been decided that the lecturer in pathology at the Sydney University shall act as honorary pathologist at the Prince Alfred Hospital and that a resident pathologist be appointed to act under his guidance. Mr. Sinclair Gillies, M.A., M.D., has been appointed honorary assistant physician; Mr. J. L. Wassell, M.B., resident registrar; Mr. J.

MacPherson, M.A, B Sc., M B, resident pathologist, and Mr W B. Walton, M.B, resident medical officer.

Obituary

A long-established and well known medical practitioner has been lost to the profession in Melbourne by the death of Mr Stephen J Burke, M R C S Eng He arrived in the colony in 1854, having been previously in the navy as surgeon on H M S *Cordelia* and in active service in the Crimean War He was a universally respected and loved practitioner, always kind and helpful to others, and his acts of charity to the sick poor made his name a household word in his district —Another much to be regretted death in the profession in Melbourne is that of Miss Amy Castilla, M.B She was one of the pioneers among the women doctors in Melbourne and the first to hold the position of resident medical officer at a general hospital in Australia—namely, at St. Vincent's Hospital, Melbourne Subsequently she filled a similar position at the Women's Hospital She then commenced private practice and was on the staff of the Queen Victoria Women's Hospital in the progress of which she took the greatest interest

Dec. 2nd, 1898.

Obituary.

SURGEON GENERAL SIR JAMES MOUAT, K C B, V.C, F R C S ENG,

HONORARY SURGEON TO THE QUEEN

THE veterans who took part in the Crimean War are fast passing away. We regret to record the death of Surgeon-General Sir James Mouat, V C, on Jan. 4th at his residence in Palace Gardens terrace, Kensington Sir James Mouat had reached the ripe age of eighty three years and had retired from the service many years ago—in 1876—but he had a long and distinguished career, as his record of military service shows, and played a notable part in his time He was essentially a man of action, endowed with much physical and mental energy as well as courage These enabled him not only to go through a good deal of arduous and responsible work and to play a prominent part in the campaigns at which he was present, but carried him on to old age in the enjoyment of life with his active habits comparatively unimpaired until nearly the end In the Crimea he displayed great energy in the field and in the official performance of his medical duties There are probably some still living who can remember him mounted on a horse with high forward action as he rode from camp to camp holding medical boards, making inspections, and giving directions in connexion with the field medical arrangements and the disposal of the sick and wounded and invalids It was at Balaclava that he won his Victoria Cross He was the son of Dr James Mouat of the 13th and 15th Light Dragoons and was born in 1815 and educated at University College and in Paris He entered the medical department of the army in 1838, was promoted surgeon in 1848, surgeon major in 1855, deputy surgeon general in 1858, surgeon general in 1864, and retired on half pay in 1876 The regimental medical system was, of course, in force during his service in the army He served in the Eastern Campaign of 1854-55 with the 6th Dragoons and on the medical staff and was in medical charge of the general field hospital of the 3rd Division throughout the siege operations until the fall of Sebastopol, and subsequently as principal medical officer of Balaclava until the final evacuation of the Crimea on June 12th, 1856, having been present at the battles of Balaclava Inkerman, and Tchernaya, and the night reconnaissance and attack on Russian outposts on Feb 19th, 1855, receiving the C.B, the Victoria Cross, the medal with three clasps, and Turkish medal, and being appointed a Knight of the Legion of Honour He was awarded the Victoria Cross for having voluntarily proceeded to the assistance of Lieutenant Colonel Morris, 17th Lancers, who was lying dangerously wounded in an exposed situation after the retreat of the light cavalry at the battle of Balaclava on Oct 25th, 1854, and having dressed that officer's wounds in the presence of the enemy He served during the New Zealand War of 1860-61 throughout the operations under General Pratt, being twice mentioned in despatches He was present in the field as Principal Medical Officer throughout the operations in the Waikato, Taranaki, and Tauranga districts in 1863-65 under Sir D Cameron and was repeatedly mentioned in despatches (medal) He received the thanks of the New Zealand Government for "special and valuable services rendered to the colony" In 1858 he was appointed Deputy Inspector General and in 1864 Inspector General of Hospitals In 1888 he was made an honorary surgeon to Her Majesty the Queen and in 1894 was created K C B

ALFRED KEBBELL, M R C S ENG.

MR KEBBELL of Flaxton, near York, who died at his residence there on Dec 21st, had an extensive practice in that district and the surrounding country He was a native of London and studied medicine at the London Hospital where he gained a surgical scholarship and held the office of house surgeon Having become qualified as M R C S Eng in 1872 he was in the following year selected to be house surgeon in the York County Hospital, an appointment which he resigned after a year's tenure in order to commence practice in Flaxton where the remainder of his life was passed Mr Kebbell was a fellow of the Obstetrical Society of London and a member of the York Medical Society Several contributions by him have appeared in THE LANCET, perhaps the most important being the description of a case of recovery after compound comminuted fracture of the skull with laceration and escape of brain matter, published in our columns on Jan 1st, 1876, followed on August 5th of the same year by an account of a case in which a girl, aged thirteen and a half years was delivered of a living child at full term The deceased was medical officer of the Fourth District of the York Union and medical officer of the Whitwell Convalescent Home He was aged fifty one years at the time of his death and has left a widow and family for whom much sympathy is felt

ROBERT FENDICK, M R C S ENG, L S A. LOND

MR ROBERT FENDICK died at his residence, Pembroke House, Whiteladies road, Clifton, Bristol, on Jan 5th, in his eighty third year Mr Fendick received his medical education at the Bristol School of Medicine and qualified as M R C S Eng in 1859 having taken the L S A Lond four years previously He shortly afterwards commenced practice in Bristol and was for many years a Poor law medical officer, being also registrar of births and deaths for one of the districts On his retirement a few years ago he was granted a superannuation allowance by the guardians During the cholera epidemic in Bristol which occurred about fifty years ago Mr Fendick, who was a member of the Cholera Committee, rendered conspicuous service Mr Fendick was for many years churchwarden of All Saints' Church He was also an active Freemason and on the occasion of his masonic jubilee in 1894 was presented with a handsome address The deceased who was well known and highly respected was one of the oldest practitioners in the West of England

PHILIP BROWN, M D ABERD

DR PHILIP BROWN of Blaydon on Tyne died at his residence near Wylam on Nov 20th after an illness of several weeks' duration The deceased gentleman who was in his seventy eighth year was born at Bishop Auckland, received his professional education at the Durham University College of Medicine in Newcastle and at University College, and became qualified as L S A in 1844 Soon afterwards he settled at Blaydon and before long had a very large practice One of his patients was the late Mr W J Linton, the artist and wood engraver who in his published memoirs testified to Dr Brown's ability and kindness In 1852 Mr Brown graduated as M D at Aberdeen University He was an energetic member of the Blaydon and Winlaton Mechanics' Institution, frequently lectured to the members, and was a constant and very popular speaker at the annual gatherings The last time the Northern Union of Mechanics Institutions met at Blaydon he was chosen President in which capacity he delivered an admirable address Dr Brown was medical officer of health of the Blaydon and Ryton Urban Districts and afterwards of the Blaydon Urban District Council On May 16th 1883, he was presented with a purse of gold and his portrait painted in oil, a gold necklace being at the same time given to Mrs. Brown. He has left several sons, one of whom is a member of his father's profession.

JOHN McCOMBIE, M.B. ABERD.

ON Dec. 23rd Dr. John McCombie died at his residence in King-street, Aberdeen, in his forty-third year. He was a native of Morayshire and after having spent some years in business in Glasgow he commenced the study of medicine in Aberdeen University, took the degree of M.B. in 1883, and *shortly afterwards* commenced practice in Aberdeen. He was greatly interested in anthropology, and on the occasion of the opening of the Mitchell Hall he lent the university a collection which was highly commended.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Haan, medical officer of the Havre hospitals.—Dr. Witold-Narkiewicz-Jodko, formerly Professor of Ophthalmology in the University of Warsaw.—Professor Laboulbène, formerly President of the Paris Academy of Medicine.—Dr. Oscar Bulhöes, Professor of Clinical Surgery in the University of Rio de Janeiro.—Dr. Boëns, a Belgian medical man who had for many years identified himself with the agitation against vaccination.—Dr. Gottlieb Gluge, Emeritus Professor of Physiology and Anatomy in the University of Brussels, has died at Nice, aged eighty-six years, having been born in Westphalia in 1812. While a student in Berlin he worked with Froriep who was prosector at the Charité and discovered the oil globules in cells undergoing fatty degeneration. After a period of study in Paris he published an important paper on Influenza treated Historically and Pathologically, for which he was awarded a prize by the Berlin Medical Faculty. In 1836 he was appointed Professor of Physiology in Brussels. His "Atlas of Pathological Anatomy" appeared in parts from 1843 to 1850. For the last twenty-three years he had been living in retirement.—Dr. Constantin Vousakis, Professor of Physiology in the University of Athens.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at meetings of the Examiners:—

Monday, Jan. 9th:

Anatomy and Physiology.—Archibald Douglas Hamilton, University College, Liverpool; Henry Shemeld Tumber and Henry Gardner, Firth College, Sheffield; Randolph Henry Neilson Rutherford, Frederick Henry Rudge, and Frank Parlett, University College, Bristol; William L'Estrange Mathews, William Edward Vaughan Lewis, and Justin James Bekenn, Mason University College, Birmingham; Austin Lewis Badcock, Charing-cross Hospital; James Douglas Judson, Owens College, Manchester; Henry Edward Barrett and Hugh George Stiles Webb, St. Mary's Hospital; Thomas Benhote Henderson, Oxford University and St. Thomas's Hospital; William Bartholomew Vaile, London Hospital; and Herbert Michael Henry Melhuish, St. Bartholomew's Hospital.

Physiology only.—Mr. Roderick McKenzie Skinner, Edinburgh University and Medical School.

19 gentlemen were referred to their professional studies for three months in both subjects and one in anatomy only.

Tuesday, Jan. 10th:

Anatomy and Physiology.—Charles Stuart Woodwark and Aubrey Keatinge Halliday Pollock, St. Bartholomew's Hospital; William Vincent Wood, Cambridge University and St. Bartholomew's Hospital; Lorimer Gifford Nash and Arthur William Gater, Guy's Hospital; Arthur Charles Nash, Guy's Hospital and Mr. Cooke's School of Anatomy and Physiology; Ernest Alfred Cox and James Duncan Clay, King's College, London; Charles Ernest Lakin and Robert Robinson Lewis, Middlesex Hospital; Charles Russ Hugh Cameron Wilson, and Ernest Edward Argles, St. Mary's Hospital; Edward Prall, Arthur Whitehead-Smith and Bertram Eli Sansom, St. Thomas's Hospital; William Ashley Beet, Charles Bramhall, William Harrington Gray, Gilbert Phillip Mosscrop, and Robert Martin Dolbey, London Hospital; Dhaupat Rai, Punjab University, Lahore; Cecil Hugh Myddelton Hughes, Westminster Hospital; and Frederick James Lawson, University College Hospital.

12 gentlemen were referred to their professional studies for three months in both subjects.

SOCIETY OF APOTHECARIES OF LONDON.—At the Primary Examination held in January the following candidates passed in the subjects indicated:—

PART I.

Biology.—L. Denny, Royal Free Hospital; I. Griffith, London Hospital and Cambridge; D. A. Stepney and M. L. Tyler, Royal Free Hospital; and J. S. Ward, Sheffield.

Chemistry.—St. C. G. Ballenden, Birmingham; J. M. Gleeson, Dublin and London Hospital; W. J. H. Hepworth, Edinburgh and St. Mary's Hospital; H. M. Huggins, St. Bartholomew's Hospital; J. Jones, Manchester; F. Marriott, Edinburgh; and G. B. Messenger, Liverpool.

Materia Medica and Pharmacy.—J. H. Bennett, Birmingham; R. V. Cowey, Edinburgh and St. Mary's Hospital; A. M. Davis, Birmingham; R. J. Hogan; J. Jones, Manchester; F. Marriott, Edinburgh; and H. E. Weston, St. George's Hospital.

PART II.

Anatomy.—J. C. Baggs, St. Thomas's and Westminster Hospitals; J. C. O. Bradbury, Cambridge; H. B. Connell, Birmingham; A. B. Edwards, St. Bartholomew's Hospital; A. T. Greenhill, Durham; R. J. Hanbury, St. Bartholomew's Hospital; A. E. Henton and W. J. H. Hepworth, Edinburgh and St. Mary's Hospital; F. P. Joscelyne, Leeds; G. J. W. Keigwin, London Hospital; N. Lipscomb and *H. Mills, St. Bartholomew's Hospital*; E. Osborne and J. R. Pooler, Birmingham; A. F. Reardon, St. Thomas's Hospital; H. H. Serpell, St. Bartholomew's Hospital; H. G. Sewell, London Hospital; G. E. Soltau, Royal Free Hospital; H. O. Sutcliffe, Cambridge; P. L. Vawdrey, St. Bartholomew's Hospital; and J. Willett, Glasgow.

Physiology.—J. C. O. Bradbury, Cambridge; P. C. Burgess, Middlesex Hospital; H. B. Connell, Birmingham; W. H. Cotton, Dublin; W. E. Cuthbertson, *Bristol and Glasgow*; A. T. Greenhill, Durham; R. J. Hanbury, St. Bartholomew's Hospital; A. E. Henton, Edinburgh and St. Mary's Hospital; E. Osborne and J. R. Pooler, Birmingham; H. G. Sewell, London Hospital; G. E. Soltau, Royal Free Hospital; P. L. Vawdrey, St. Bartholomew's Hospital; *and J. Willett, Glasgow.*

UNIVERSITY OF LONDON.—At the B.S. examination for honours the following candidates were successful:—

Surgery.—First Class: John Preston Maxwell (Gold Medal), St. Bartholomew's Hospital. Second Class: Thomas Varley Cunliffe, Owens College and Manchester Royal Infirmary; and Donald John Munro, Guy's Hospital. Third Class: Winifred Secretan Patch, B.Sc., Royal Free Hospital and London School of Medicine.

FOREIGN UNIVERSITY INTELLIGENCE.—*Baltimore:* Dr. J. Williams Lord has been appointed Professor of Dermatology in succession to Dr. Gilchrist, resigned.—*Berlin:* There are this winter session more students in the medical faculty than there have ever been before, the number being 1311.—*Bologna:* Dr. G. Valenti of Catania has been appointed to the chair of Anatomy.—*Erlangen:* Dr. L. R. Müller has been recognised as *privat-docent* in Medicine.—*Genoa:* Dr. Novaro of Bologna has been appointed Extraordinary Professor of Clinical Surgery in succession to the late Dr. Caselli.—*Halle:* Dr. E. Mehnert of Strasburg has been appointed Extraordinary Professor of Anatomy.—*Kiel:* Dr. Heermann has been recognised as *privat-docent* of Otology.—*Nancy:* Dr. Weiss has been appointed Professor of Clinical Surgery.—*Zürich:* Dr. Max von Frey of Leipsic has been appointed to the chair of Physiology.

UNIVERSITY OF CAMBRIDGE.—Dr. Hill, Master of Downing College and Vice-Chancellor of the University, has been reappointed University Lecturer in Advanced Human Anatomy until Michaelmas, 1903.

WE are informed that the "Antikamnia Chemical Company" have complained to the authors of the Extra Pharmacopœia of the publication of the paragraph therein regarding Antikamnia and that the authors have withdrawn it as being incorrect.

CORPORATE AND MEDICAL REFORM ASSOCIATION.—The Corporate and Medical Reform Association, Limited, 2, Southampton-street, Strand, has prepared a memorial to the General Medical Council praying for the restraint of "illegal certificates of proficiency in departments of medicine, surgery, or midwifery on less than that full medical education which the law requires as necessary for the public safety." A memorial on the same subject was presented to the Council on the concluding day of last session, whereupon Mr. George Brown moved and Mr. Victor Horsley seconded the appointment of a special committee to examine the question. The motion was supported by Dr. Glover, Dr. William Bruce, Sir William Thomson (a unanimous vote of the Direct Representatives), Sir Christopher Nixon, Dr. E. Bennett, and Mr. Tichborne; but an amendment, moved by Dr. MacAlister, that the memorial be referred to the Executive Committee was carried by a majority of 5—a method of disposing of the memorial which the association considers to be not the most advantageous. The object of the second memorial, to which signatures are now invited, is to strengthen the hands of the Direct Representatives and their friends on the Council. The certificates specially named by the association in the memorial are: (1) "every certificate of proficiency in any class of midwifery except those certificates which admit to the Medical Register"; and (2) the certificates granted to makers and vendors of spectacles by the Spectaclemakers' Company and the British Optical Association.

The Vestry of St. George-the-Martyr, Southwark, and the Supply of Diphtheria Antitoxin.—On Jan. 11th, 1898, this vestry in accordance with a recommendation of its Public Health and Sewers Committee resolved that a supply of diphtheria antitoxin should be kept for the use of medical practitioners in the event of the hospitals of the Metropolitan Asylums Board being full. This provision of antitoxin by a public body is an excellent and enlightened policy and one which has already been adopted by several local authorities, but a retrograde spirit seems now to have taken possession of the above-mentioned committee, for at the meeting of the vestry on Dec. 13th, 1698, it was moved on behalf of the committee that the resolution of Jan. 11th should be rescinded on the ground that antitoxin "should be injected only by medical men who have a thorough and continuing practical knowledge of the use and effects of the serum—namely, the medical staff of the Asylums Board." Dr. F. J. Waldo, the medical officer of health, pointed out to the vestry that the antitoxin treatment was no longer on its trial but was adopted by medical men in all countries. The experience of the Asylums Board hospitals was that a notable decrease in the mortality had followed its introduction about the year 1895. Its success was especially marked in post-scarlatinal diphtheria, most probably on account of the patients being brought under treatment at an early stage of the disease. Great advantages are to be expected from its use in private practice, for the delay caused by waiting for vacant beds at hospitals adds to the death-rate. Two vestrymen said that *nothing ought to* be done which would tend to the poor being treated at home instead of at the hospital. In the *result the consideration* of the matter was adjourned for six months.

Presentations to Medical Men.—The esteem in which Mr. C. P. O'Connor, M.D. Durh., of March, Cambs, is held among his numerous patients was still further emphasised on Dec. 16th, 1898, when he was the recipient of a silver salver, beautifully engraved, subscribed for by no less than 276 employés engaged on the Great Eastern Railway at March. The salver bears the following inscription: "Presented to Dr. C. P. O'Connor by the railway men at March and Whitemoor on the occasion of his marriage, Oct. 21st, 1898."—On Dec. 20th, 1898, at the annual distribution of certificates to the successful candidates in the local St. John Ambulance Classes at Loughboro', Leicestershire, the Mayor of the borough presided, and on behalf of the female class presented Mr. P. Phelps, L R C.P. Edin., M.R C S. Eng., of Loughboro', with a silver-mounted walking stick, suitably engraved, and a similar walking stick was handed to Mr. J. B. Pike, L.R C.P. Edin, M.R C S Eng., from the male class, both as tokens of thanks for their instructions on First Aid—On Dec. 23rd, 1898, the annual conversazione and presentation of certificates and medallions of the Rutherglen Ambulance Class took place in the lesser town-hall. Provost Edmiston occupied the chair and on presenting in the course of the evening Mr. R. Clarke, M B Glasg., of Rutherglen, the lecturer, with a handsome oak escritoire referred to the great success which had attended the year's class, which was a record one in its history.—At the monthly meeting of the Visiting Committee of the Plymouth Borough Asylum at Blackadon on Dec 28th Mr. Arthur N. Davis, L.R C P. & S. Edin., the medical superintendent, who is about to leave for the Devon County Asylum, was presented by the Mayor on behalf of the committee with a framed and illuminated address on vellum in which was set forth their appreciation of the services of Mr. Davis in his management of the institution during the past seven years.—At the annual supper of the officers and staff of the Plymouth Borough Asylum held on Jan. 2nd the superintendent-elect of the institution presented Mr. Davis with an engraved electro-plated soup tureen and entrée dish bearing the following inscription: "Presented to Dr. Arthur N. Davis by the officers and staff of the Plymouth Borough Asylum as a token of their esteem on the occasion of his appointment as medical superintendent of the Devon County Asylum."

A general meeting was held on Thursday afternoon of the East Suburban Medical Protection and Medico-Ethical Society, Limited, at which an annual report of considerable interest was presented by the officers of the society.

Unqualified Practice in Devonshire.—At an inquest held at Modbury, Devonshire, on Jan. 6th relative to the death of a quarryman, aged fifty-nine years, it was stated that the deceased paid £2 10*s*. to a man named Roberts of Plymouth who advertised that he could "cure cancer and diabetes", and in return he received twenty-two powders which on analysis were found to consist of table salt. Death was due to diabetic coma.

Health of Bristol.—Dr. D. S. Davies (the medical officer of health) reported at the meeting of the Bristol Health Committee held on Jan. 3rd that the annual death-rate for 1898 was 17·1 per 1000 which is the same as that recorded for 1897 and compared favourably with the ten years' average which is 18·4 per 1000. The birth-rate was 28·5 per 1000, the ten years' average being 29·4 per 1000. The death-rate from zymotic diseases during 1898 was 2·68 per 1000.

The Police and Vaccination.—At the last meeting of the Cornwall Standing Joint Committee a member drew attention to the fact that some of the police made conscientious objections to vaccination; he also inquired whether police constables were vaccinated. The chief constable replied that he had heard of no police-officer making objections to vaccination and added that there was no compulsion for the members of the force themselves to be vaccinated. Another member stated that four or five policeman had applied for exemption in his district.

Literary Intelligence.—According to *Le Scalpel* there has just been a considerable mortality amongst French medical journals, *La Revue des Sciences Médicales de Hayem*, *Le Journal des Connaissances Médicales* (which has existed for fifty-six years and has of late been edited by Professor Cornil and Dr. Galippe), and *Le Journal des Maladies Nerveuses* of Paris having ceased to appear.—Messrs. Kegan Paul and Co. will have ready by the middle of January a new and entirely revised edition of Mr. E A. Reynold-Ball's "Mediterranean Winter Resorts."

Freemasonry.—*The Rahere Lodge, No. 2546.* An ordinary meeting of this Lodge was held at Frascati's Restaurant, Oxford-street, W., on Tuesday, Jan. 10th, 1899, Bro. Burns, the W M., in the chair. Messrs. F. H. Lewis, W. W. Kennedy, and T. Hood were initiated into freemasonry and Bro. J. A. Rigge was elected a joining member of the Lodge. Bro Dr. Roberts was admitted to the second degree and Bros. Coventon, Griffiths, and Gay to the third degree. A sum of 20 guineas was voted from the funds of the Lodge in aid of the Royal Medical Benevolent College, Epsom, and 1 guinea was given to the Home for the Dying. The brethren and their guests afterwards dined together.

Complimentary Farewell Dinner.—On Dec. 15th, 1898, Mr. J J. F. Bourke, L R C P. & S Irel., of Rathgar, Dublin, was entertained at a farewell and complimentary dinner by some of his colleagues of the Richmond and Temple-street Hospital and by some personal friends. In both those institutions Mr. Bourke became very popular and those who had worked with him availed themselves of the opportunity which his leaving to take up an important appointment in Australia afforded to pay him some mark of esteem and appreciation. Dr. T. Myles presided and in proposing the health and success of the guest of the evening expressed the regret of all present at the loss which they must sustain by Mr. Bourke's departure.

A New Mortuary at Hammersmith.—A new mortuary and coroner's offices were recently opened at Fulham Palace-road. The accommodation in the front block provides for the court, lobby and entrance, waiting room, coroner's room, lavatories and closet accommodation on the ground-floor, with caretaker's rooms above the waiting- and coroner's rooms; there is a 10 ft. passage entrance and exit at each end leading to the open yard 20 ft. wide. The mortuaries are on the east side of the open yard and consist of No. 1, ordinary mortuary, and No. 2, mortuary for infectious cases, separated by a lobby. Adjoining the No. 1 mortuary is the post-mortem room, and close by is the laboratory. A wash-house is situated at the north end of the block, and a shell-house and disinfecting house at the other end. The general plan has been arranged to keep the various buildings separate, with sufficient air space between each. The coroner, jury, and witnesses and other persons wishing to see the bodies can do so from the viewing lobby. The court is in the front of the building and measures 20 ft. by 30 ft.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BENSON, FRANCIS ALOYSIUS, L.R.C.S., L.R.C.P. Irel., has been appointed Public Vaccinator for the Ormesby District of the Middlesbrough Union.

BROWN, RICHD., M.B. Durh., B.S., has been appointed Medical Officer by the Blaydon District Council, vice P. Brown.

COOPER, C. W., M.B., M.R.C.P. Lond., has been appointed Honorary Consulting Physician to the Leicester Infirmary.

DAVIES, A. O., M.R.C.S., L.R.C.P. & S. Edin., has been appointed Medical Referee under the Workmen's Compensation Act for the Aberystwith, Machynlleth, and Dolgelly districts.

DAWNAY, A. H. PAYAN, M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to the Royal Orthopædic Hospital.

GARRETT, J. H., M.D. Durh., D.P.H. Camb., has been re-appointed Medical Officer of Health for the Borough of Cheltenham.

GRAY, SARAH, L.R.C.P., L.R.C.S. Edin., L.F.P. & S. Glasg., has been appointed Assistant Surgeon for the Nottingham Hospital for Women.

GREENWOOD, FRANK R., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Surgical Officer for the Birmingham and Midland Free Hospital for Sick Children.

GUNTHER, T., M.D. Tübingen, L.R.C.P. Lond., has been re-appointed Medical Officer of Health by the Hampton Wick Urban District Council.

KNOX, J. E., M.B., C.M. Edin., has been appointed Medical Officer for the Molesey Sanitary District of the Kingston Union.

MORRISON, D. S., M.B., C.M. Edin., has been appointed Medical Officer for the Liff Landward District by the Dundee Parish Council.

OSBORNE, O., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Bexhill Urban District Council.

PECK, H., M.B. Edin., L.R.C.P., L.R.C.S., D.P.H. Camb., has been appointed Medical Officer of Health for the Chesterfield Rural District, vice A. Mackintosh.

PRATT, REGINALD, M.D. Lond., M.R.C.S., has been appointed an Honorary Physician to the Leicester Infirmary, vice C. W. Cooper, resigned.

PUGH, ROBT., M.B., Ch.B. Edin., has been appointed Junior Assistant Medical Officer for the City Asylum, Birmingham.

ROSS, J. S., M.B., Ch.B. Vict., has been appointed House Surgeon and Resident Obstetric Assistant Surgeon for the St. Mary's Hospital, Manchester, vice W. K. Walls.

ROWLAND, J. T., M.D. St. And., M.R.C.S., has been re-appointed Medical Officer of Health by the Richmond Urban District Council.

SEVESTRE, R., M.D. Camb., L.R.C.P. Lond., M.R.C.P., has been appointed an Assistant Honorary Physician to the Leicester Infirmary.

SMITH, C. C., M.B. Camb., M.R.C.S., has been appointed Medical Officer for the Redditch Sanitary District of the Bromsgrove Union.

THOMSON, H. CAMPBELL, M.D. Lond., M.R.C.S., has been appointed Pathologist and Curator of the Museum to the Middlesex Hospital.

WITHERS, J. S., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Sale Urban District Council.

WOOD, A. J., M.B., C.M. Edin., has been appointed Senior Medical Officer for the Poole Medical Association.

Vacancies.

For further information regarding each vacancy reference shoul made to the advertisement (see Index).

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park.—Pathologist. Salary 100 guineas per annum.

CONSUMPTION HOSPITALS AND ORPHAN HOMES OF SCOTLAND, Bridge of Weir.—Resident Medical Officer. Applications to the Hon. Secretary, 141, West George-street, Glasgow.

FARRINGDON GENERAL DISPENSARY AND LYING-IN CHARITY, 17, Bartlett's Buildings, Holborn, London.—Honorary Dental Surgeon. Also Resident Medical Officer. Salary £100 per annum, with apartments and attendance.

FINSBURY DISPENSARY, Brewer street, Goswell-road, E.C.—Resident Medical Officer. Salary £120 per annum, with a furnished residence in the Institution, and attendance, coals, and gas.

GENERAL HOSPITAL, Nottingham.—House Physician for two years. Salary £100, rising £10 a year to £120, with board, lodging, and washing.

HULME DISPENSARY, Manchester.—House Surgeon. £130 per annum, with apartments, coal, and gas.

JAFFRAY BRANCH OF THE GENERAL HOSPITAL, Gravelly-hill, near Birmingham.—Resident Medical and Surgical Officer. Salary £150 per annum, with board, residence, and washing.

LIVERPOOL DISPENSARIES.—Two Assistant Surgeons, unmarried. Salary £80 for the first year and £90 per annum afterwards, with apartments, board, and attendance. Applications to the Secretary, 34, Moorfields, Liverpool.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Assistant Surgeon.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant for at least one year. Salary £120 for the first year and £160 afterwards.

NORTHAMPTON GENERAL INFIRMARY.—Assistant House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, and washing.

ROYAL SOUTH LONDON DISPENSARY, St. George's-cross, S.E.—Honorary Surgeon.

SEAMEN'S HOSPITAL SOCIETY, Greenwich, S.E.—House Physician for *Dreadnought* Hospital, Greenwich. Salary £75 per annum, with board and residence. Also Surgeon for Dispensary, 51, East India Dock-road, E. Salary £63 per annum.

ST. MARY'S CHILDREN'S HOSPITAL, Plaistow, E.—Senior Resident Medical Officer for one year. Salary £80 per annum, with residence in the hospital, board, and washing.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W.—Ophthalmic Surgeon.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon for six months. Board, lodging, and washing provided. Gratuity £20.

WEST DERBY UNION.—Resident Assistant Medical Officer for the Workhouse, Rice-lane, Walton-on-the-Hill, Liverpool. Salary £100 per annum, with first-class rations, apartments, &c. Salary subject to statutory deduction. Applications to the Union Clerk, Brougham-terrace, West Derby-road.

Births, Marriages, and Deaths.

BIRTHS.

FORD.—On Jan. 6th, at Ladbroke-square, W., the wife of Frank C. Ford M.B., of a son.

LUCAS.—On Jan. 9th, at Broadway House, Tooting, the wife of Claude R. Lucas, M.R.C.S., L.R.C.P., of a son.

MOORE.—On Dec. 27th, at Oakdene, Walton-on-Thames, the wife of S. J. Moore, M.D., of a daughter.

REES.—On Jan. 8th, at Holmesdale, Penarth, South Wales, the wife of J. Hugh Rees, M.D., of a son.

WORNUM.—On Jan. 8th, at Belsize-park, N.W., the wife of George Porter Wornum, M.R.C.S., of a daughter.

MARRIAGES.

HASTINGS—MUNDELLA.—On Jan. 5th, at St. Mark's, Regent's-park, N.W., by the Rev. J. Sparrow Simpson, Edwin Birchall Hastings, M.D., youngest son of the late William Hastings of Huddersfield, and Theresa, second daughter of the late John Mundella of Nottingham.

HOLME—LAYNG.—On Jan. 4th, at S. Andrew's, Rippingale, Crampton W. Holme, M.R.C.S., Wisbech, to Ethel Mary, eldest daughter of Rev. W. W. Layng, Rector of Rippingale.

HUIE—INGLIS.—On Jan. 4th, at St. Peter's Church, Ashby Parva, Leicestershire, Henry Greville Huie, M.D., to Ida Mary, eldest daughter of C. J. Inglis, Esq.

NIGHTINGALE—COLLISON.—On Jan. 7th, at St. Mary Abbot's, Kensington, Percy Athelstan Nightingale, M.D., second son of the late Percy Nightingale, to Muriel Stoughton, third daughter of the late Charles Stoughton Collison, of Upper Phillimore-gardens, Kensington, W.

SMYTH—BULLOCK.—On Jan. 3rd, at C.M.S. Church, Ningpo, China, Richard Smyth, B.A., M.B., Medical Missionary, to Blanche Emily, second daughter of the Rev. Charles Bullock, B.D., Coomrith, Eastbourne.

TAYLOR—PEECH.—On Jan. 7th, at Holy Trinity Church, Rochampton, S.W., Alfred Ernest Taylor, M.B., B.S. Lond., F.R.C.S. Eng., of Lancaster-gate, W., to Mary Emma, eldest daughter of William Peech, of Fern Bank, Roehampton-park, S.W.

WILLIS—THRING.—On Jan. 5th, at St. Peter's, Bournemouth, Cryll Hamer Willis, M.R.C.S., L.R.C.P. Lond., younger son of the late M. M. Willis, of Beckenham, Kent, to Annie Bertha, youngest daughter of the late Robert Thring of Winchester.

DEATHS.

ARMSTRONG.—On Jan. 5th, suddenly, at 3, Bentinck-villas, Newcastle-upon-Tyne, Mary, dearly beloved wife of Henry E. Armstrong, Medical Officer of Health.

FARR.—On Jan. 11th, suddenly, at Penrhyn Lodge, Cambridge-park, Twickenham, George Frederick Farr, L.R.C.P., M.R.C.S., in his 67th year.

MOUAT.—On Jan. 4th, at Palace-gardens-terrace, Kensington, Surgeon-General Sir James Mouat, K.C.B., V.C., Q.H.S.

SEWELL.—On Jan. 2nd, at Mentone, James Arthur Sewell, M.D., of Les Ecureuils, Quebec, late H.M.'s Bengal Medical Service.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat (2 P.M.).

TUESDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (18th).—St. Bartholomew's (1.30 P.M.), University College, (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. *Ormond street* (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (19th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.).

FRIDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (21st).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (16th).—SOCIETY OF ARTS.—8 P.M. Dr S. Rideal: *Bacterial* Purification of Sewage. (Cantor Lecture.)

TUESDAY (17th).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. A. Barker: Final Sequel to a Case already reported of Removal of Cystic Disease of a supposed Accessory Thyroid (illustrated by lantern slides).—Mr. T. Carwardine: Lantern Photographs of a Case of Molluscum Fibrosum with *Neuroma of the* Brachial Plexus.—Dr. H. P. Potter: Crushing Fracture of the Cervical Spine.—Dr. R. Crawfurd: Cystic Suprarenal Bodies.—Dr. H. D. Rolleston: Cysts in Suprarenal Body.—Dr. M. Fletcher: Tuberculous Cholangitis.—Mr. H. B. Robinson: Multilocular Tumour from Inguinal Canal in a Female.—Mr. C. P. Beadles: Lesion of Pancreas with Fat Necrosis. Card Specimens:—Mr. Carwardine: (1) Papilloma of Rectum discharged *spontaneously*, (2) Enucleated Prostatic Myomata associated with Vesical Calculus.—Mr. Beadles: Healed Perforation of Duodenum after Passage of Gall-stones.

CHELSEA CLINICAL SOCIETY (Holy Trinity Parish Hall, Pavilion-road, S.W.).—8.30 P.M. Papers.—Dr. J. H. Dauber: A Plea *for Greater* Attention to Asepsis in Hospital and Private Practice.—Dr. C. O. Gibbes: Pathology of Mitral Stenosis (addenda to paper read last meeting).—Dr. J. Blumfeld: Administration *of Ether to Infants* and Young Children.

WEDNESDAY (18th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. President: Annual Address.

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Gt. George-street, Westminster, S.W.).—7.30 P.M. Ordinary Meeting. 7.45 P.M. Report of the Council. Election of Officers and Council. Mr. F. C. Bayard (President): *The Government* Meteorological Organisations in Various Parts *of the World* (illustrated by lantern slides).

NORTH-WEST LONDON CLINICAL SOCIETY (North West London Hospital).—8.30 P.M. Monthly Demonstration of Clinical Cases.

THURSDAY (19th).—HARVEIAN SOCIETY OF LONDON (Stafford *Rooms*, Titchborne-street, Edgware-road).—8.30 P.M. Annual General Meeting. Election of Officers. Presidential Address. Annual Conversazione.

FRIDAY (20th).—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Paper:—Dr. B. Low: Epidemic Cerebro-Spinal Meningitis.

SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—8.30 P.M. Continuation of Adjourned Discussion on Selection of an Anæsthetic.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (16th).—WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. S. Edwards: The Methods of Examining the Bladder and Rectum.

TUESDAY (17th).—ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. E. Ray Lankester: The Morphology of the Mollusca.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Sir W. Gowers: Epilepsy.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—4 P.M. Dr. T. D. Savill: Cases of Infantile Paralysis.

THURSDAY (19th).—LONDON TEMPERANCE HOSPITAL.—2 P.M. Clinical and Pathological Demonstration to Senior Students.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. S. Edwards: The Methods of Examining the Rectum and Bladder.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Boyd: Demonstration of Surgical Cases. (Post-Graduate Class.)

FRIDAY (20th).—ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. Dewar: Liquid Hydrogen.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1898, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 6*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

PROFESSIONAL UNION.

WE have noted in another column that a general meeting was held yesterday (Thursday) afternoon of the East Suburban Medical Protection and Medico-Ethical Society, Limited, and a perusal of the annual report of the society makes us select the large subject of Professional Union for a few words of exposition.

The East Suburban Medical Protection and Medico-Ethical Society, which has been formed to promote the interests of medical practitioners in the East of London and in suburban Essex, was called into being by an attempt on the part of the Plaistow Maternity Charity and District Nurses' Home—a pseudo-charitable institution with the methods of which readers of THE LANCET have been kept fully informed (*Abuse of Nursing Charities*, THE LANCET, August 27th and Sept. 17th and 24th, 1898)—to establish a branch in East Ham. A meeting of the local medical profession was held at the beginning of the year in protest against the project of development planned by the Maternity Charity with the result that to a certain extent that project was abandoned. Encouraged by the swift success that followed upon this show of a united front a larger meeting was then held at Stratford and as a result a society was formed and incorporated bearing the title we have already quoted and designed to protect its members against all unfair competition and to safeguard their material interests. In the memorandum of association, a most comprehensive document, the society is said to be established for the purpose of mutual helpfulness in forming a common fund by the contributions of its members ...... to maintain the status of registered medical practitioners, to assist them in carrying on their profession ...... by (among other things)—

(a) Investigating abuses in medical charities;
(b) Attempting to obtain adequate representation of medical practitioners on the governing bodies of medical charities;
(c) Attempting to suppress medical aid societies and clubs which are not carried on by duly registered medical practitioners and in an honourable, professional, and satisfactory manner; and
(d) Establishing a public medical service, a hospital or dispensary, chiefly managed by registered medical practitioners, if and when desired by a majority of the members in general meeting assembled.

There are many other objects set down—in fact, the alphabet is well-nigh exhausted in enumerating them—but all the others, as well as the ones we have quoted, are covered by "(q) To support and safeguard the interests of duly registered medical practitioners" and need not be enumerated now. They deal with such matters as legal protection, debt-collecting, and the establishment of an agency for the transfer of practices.

The first four objects which this young society has set before it seem to us to comprise in themselves an excellent reform programme. If the society can by united effort carry out these in reality as well as in name they will set an example to other medical men everywhere of how to form a professional union (which is not a trades' union). To investigate medical charities has now become the duty of every medical man towards his neighbour and towards himself. The one thing that a "charity" is always ready to give away is medical aid. Let all medical men see that the institutions which offer free or on ludicrous pecuniary terms the services of our profession are managed solely and truly for the benefit of the suffering poor and not for the profit or social aggrandisement of persons richer than the medical men to be exploited. It is well known to all our readers that many so-called "medical aid" societies have only one benefit to offer the members of their association and that is professional attendance when sick, but that in spite of this the unfortunate officers of such societies are underpaid, while they are made the instruments to destroy professional union. The development of those societies which allow all and every person regardless of their incomes to exact service from medical men should be stoutly resisted by medical men in the interests of the public and especially of the suffering poor who lose by their agency the ministration properly due to them. And the most effectual resistance which can be offered is the organisation by the local medical men of a real medical aid society, one which will offer to those whose circumstances make them proper subjects for club treatment good and thoughtful medical treatment by practitioners of standing and experience.

A NEW CASE-PAPER.

MESSRS. JOHN WRIGHT AND CO. of Bristol have sent us some specimens of a new case-paper designed by Mr. J. K. Couch and Dr. E. Le C. Lancaster. On the one side are the usual headings of "Family History," "General Condition," "Respiratory System," and the like, while on the other side are diagrammatic figures of the chest and pelvis from both the back and the front. There are also diagrams of the larynx, the posterior nares, the palatal arch, the tongue, and the soles of the feet. There are in addition views of the side of the face and head, a sagittal section of the female trunk, a view of the female pelvis from above, and plans of the hands and feet. The price is 15s. per 500 or 26s. per 1000, or bound in books of 250, indexed and numbered, 11s. They seem to us to be eminently compact and should prove very useful as a means of keeping a shorthand record of a case.

THE MOTOR TRICYCLE.

To the Editors of THE LANCET.

SIRS,—As a country practitioner I would like to ask if any of your subscribers have any experience of the motor tricycle, and if so, whether they can recommend such means of locomotion to medical practitioners who have long journeys to make.

I am, Sirs, yours faithfully,
OMICRON.

Jan. 10th, 1899.

LYCETOL.

To the Editors of THE LANCET.

SIRS,—The action of lycetol in three cases that have come under my observation has been so marked that I am induced to record my experience and to ask any of your readers who may also have used it whether their experience is similar to mine or whether the results obtained when I was using it were merely a matter of accident. The first case was one of gouty sciatica of more or less intensity for about two years. During a desultory conversation not long since the preparation was accidentally alluded to as having been beneficial in similar instances and though at the time sceptical as to any probable good that might result I decided to try it. After its exhibition for ten days or so very great improvement was apparent. At the end of a month every trace of sciatica had disappeared and it has not since returned. The second case was one of rheumatic arthritis involving both carpal joints, especially the left, and the first phalanx of the left thumb. There was great pain, tenderness, and enlargement of both joints. Lycetol was given in the usual doses of from 8 to 15 grains twice daily, at 11 A.M. and 4 P.M., and on two occasions it was taken thrice during the day. Within six days the pain had practically ceased and within seventeen days the swelling and tenderness in each wrist had greatly subsided, the right one being nearly normal in size and the swelling in the left although not so markedly decreased is still becoming reduced. The third case was not that of a patient but of a brother practitioner who for many weeks had been suffering from gout and whose system was saturated with uric acid. I met this gentleman a few weeks since and related my experience to him as above. As he had been ill for some time with no marked abatement he elected to try lycetol. I heard from him a few days since and he says that the preparation "has done wonders for him" and he "will not be without it for the future." No other treatment was adopted or any other drug used while lycetol was being taken and it was administered in alkaline effervescent mineral water.

I am much interested to learn what it may have done in the hands of others in order to judge whether the rapid improvement in the three instances I have related may be fairly attributed to its use or whether it is to be viewed merely as a series of remarkable coincidences. Should the former prove to be the case we are probably in possession of a valuable adjunct in the treatment of rheumatism and gout and their allied disorders.—I am, Sirs, yours faithfully,

Jan. 3rd, 1899. INQUIRENS.

WANTED A HOME FOR A CASE OF ASTHMA.

To the Editors of THE LANCET.

SIRS,—I would feel obliged if you could inform me through THE LANCET of any places recommended for asthma, and especially of any sort of convalescent home or institution where a case could be taken in; a moderate weekly payment if necessary could be made. The patient is a young woman of about twenty-five years of age, and is a milliner by trade. The case is of the bronchial type and, as far as I can make out, suited by a mild, rather moist air, sheltered from high cold winds.

I am, Sirs, yours faithfully,
CANTAB.

Jan. 9th, 1899.

*** We cannot recommend with any confidence a place that will be suitable for a particular case of asthma. From what our correspondent tells us we think that either Bournemouth or Torquay or else Ilfracombe might perhaps be tried with advantage. Our advertisement columns may give our correspondent the advice which he seeks with regard to a suitable home.—ED. L.

WHY IS THE FEE WITHHELD?

To the Editors of THE LANCET.

SIRS,—May I ask your opinion on the following case? On Christmas morning I was called to see a child suffering from severe burns about the body. I duly attended and thoroughly dressed the child and ordered removal of the patient to the local cottage hospital where I am an honorary medical officer. I saw the child two hours after admission. The child died the same night. An inquest was held and I was called to give evidence. I claimed a fee as I gave evidence about what had occurred in my private practice. The child was never redressed in the hospital so that I could only speak as to the injuries I had seen outside. Am I right in claiming a fee, for it has been refused? Thanking you in anticipation of your answer,

I am, Sirs, yours faithfully,
M.R.C.S.

Jan. 10th, 1899.

*** Under the circumstances narrated we consider that our correspondent is entitled to a fee. He did not treat the patient or attend the inquest save in a private capacity.—ED. L.

FORMALDEHYDE DISINFECTION.

THE Chicago *Railway Surgeon* of Nov. 15th, 1898, states that the Chicago Health Department has abandoned all forms of lamps, autoclaves, and other apparatus for the production of formaldehyde. The disinfectors of the department fumigate some 1200 premises annually. They are now furnished with a bottle of formalin (a 40 per cent. solution of formaldehyde gas in water), several sheets are hung up in the appartments to be disinfected, and the solution is sprayed over them, about 150 c.c. (5 fl. oz.) of the solution to each thousand cubic feet being used. The windows and any cracks there may be are sealed up before the fumigation, and the room is then left for at least four hours. Control cultures of various micro-organisms left in the rooms during the fumigation are entirely killed.

EUCAINE.

To the Editors of THE LANCET.

SIRS,—Would you inform me (1) if eucaine is safe to use hypodermically in *infants and young children* as a local anæsthetic, and if so in what strength and quantity? (2) What is an efficient strength for painting mucous membranes to produce local anæsthesia in small operations like removing nasal mucous polypi, tonsillotomy, &c.?

(3) What is the best method of preparing a solution that will keep without deterioration or decomposition? (4) In spasmodic rigidity of the os uteri in the first stage of labour is the local application of eucaine an efficient substitute for chloral internally and chloroform inhalation? If so, when should it be preferred to the above remedies, is there any danger in its use, and what is the *modus operandi* of its application? If you or any of your correspondents would give me the above information or refer me to any literature that will answer these questions I should be very grateful

I am, Sirs, yours faithfully,

Jan 8th, 1899. IGNORAMUS

*** 1. We do not think sufficient is known of the action of eucaine to make it safe to use as an injection for infants Professor Ponchet read a paper in 1897 before the Société de Thérapeutique showing eucaine to be a dangerous cardiac depressant. 2. From 5 per cent to 8 per cent is the usual strength of the solution of hydrochloride of eucaine necessary to produce anæsthesia for such minor operations. A paper has been read by Dr Maclennan and the late Professor Charteris on eucaine before the Royal Society of Edinburgh Perhaps our readers can give "Ignoramus information on other points in his letter —ED L.

CAULS

A LETTER has been received by a correspondent, a medical man, asking him if he feels disposed to buy a caul or, in case the article is of no use to him if he can recommend an establishment where cauls are purchased. We believe that there is still some market for cauls among sailors who retain their belief in the efficacy of the membranes as a protection against shipwreck and drowning and we endorse the advice given by our correspondent to try the mercantile marine Notices of "Cauls For Sale Within were to be seen recently in windows in the vicinity of the docks both of London and Liverpool but it is some time since we have noticed an advertisement of a caul for sale in the daily press It may be remarked that the sale of cauls so far from being a very ancient custom is a comparatively modern innovation. The witchcraft of the Middle Ages declared against the caul retaining any virtue whatever if parted with by gift or sale to any but a member of the child's kindred Probably it was the midwife as is pointed out in "Credulities Past and Present, by Mr W Jones, who discountenanced this exclusive view of the matter and proceeded to turn the accident of parturition into coin of the realm

"A SANITARY COFFIN"

NEARLY a year ago Mr C S Bowker of Cwmbrau House, Newport, Monmouthshire, sent us a model of what he describes as a sanitary coffin, requesting us to express our opinion upon it. The coffin is constructed of thin metal lined with porous ware. It is closed by porous tiles luted with plaster of Paris. Carefully following the inventor's directions we placed the body of a rabbit in the coffin and sealed it up in the manner directed. At no time did the coffin appear to be offensive After several months the body of the rabbit had shrunk considerably and liquefied The contents, however, were decidedly less offensive than would be the case under other circumstances. The principle appears to be that during the process of putrefaction the offensive gases evolved pass through the porous ware, thus coming into intimate association with the oxygen of the air In this way deodorisation and destruction of the gaseous putrefactive products are to some extent effected.

FOR ONE SHILLING!

To the Editors of THE LANCET.

SIRS,—The following little episode occurring this morning in my practice will I think, interest your readers and the profession generally, while it may serve at the same time to reveal the abyss of degradation to which we are fast hastening A young married woman was shown into my consulting room and forthwith informed me that she presented herself for the purpose of being medically examined for a club which she proposed to join. She thereupon handed me a paper and hastily scanning it down I found one side already filled up presumably by herself, with answers to questions of a personal character but turning the paper over I found as heading "National Deposit Friendly Society, Medical Examination Form, and immediately beneath this appeared the following legend:—

"*Any Registered Medical Practitioner will make the Examination for the Fee of 1s*"

When I had recovered myself I inquired whether this was the fee she expected to pay for my examining her and she replied that she was given to understand that such was the fee the medical man was entitled to Handing her back the paper—to her evident astonishment—I intimated grave doubts as regards *any* registered medical practitioner so far forgetting both himself and his profession but I suggested that if she wrote to the 'National Deposit Friendly Society' it was quite likely they would send down to Windsor one of their own so-called medical officers who for that princely remuneration might be willing to oblige her She promised to write and left quite charmed with the dazzling prospect. Now Sirs, we have seen much of change and so-called advancement in this eventful century but never aught like this—appraised and knocked down at 1s in favour of the 'National Deposit Friendly Society" the skilled labour and scientific research of any registered medical practitioner of Great Britain and Ireland!

I am Sirs yours faithfully,

New road, Windsor Jan 10th 1899 W. LISLE GOODRIDGE.

THE PUBLIC COST OF QUACKERY.

AN inquest was held at Coventry last Saturday on the body of a child who had been attended by a Mr Millerchip, also styled "Dr" Millerchip A few hours before the child died a medical man was sent for on the advice of Millerchip. At the inquest the medical man testified that the deceased had died from laryngitis and pneumonia and in his summing up the coroner, Mr. C W. Iliffe, pointed out that such cases entailed a great and unnecessary expense upon the ratepayers, as the necessity for the inquest arose simply out of the employment of unqualified persons as medical men. These people could not give death certificates nor could qualified men if they were only called in a few hours before the death of the patient, and consequently inquests became necessary We take our account of the case from the *Midland Daily Telegraph* and we see that the coroner's officer during the proceedings put in a letter from our contemporary's columns in which Millerchip stated that he was a qualified medical man There is no one of this name in the current issue of the Medical Register, but a Thomas Millerchip was removed from the Register in November, 1885 having been sentenced to ten years penal servitude for procuring abortion

◆

Reader—There is no such book as "The Earl and the Doctor." The title of the book is "South Sea Bubbles," the authors being described as 'The Earl and the Doctor" The book, a lively and unconventional account of a tour in Polynesia, was written by the late Earl of Pembroke and the late George H Kingsley, a medical man and a brother of the more famous writers Charles and Henry Kingsley.

A B—"Anatomy for Nurses" is a good little book which might be suitable for the purpose, and the first two lectures in Mr. Osborn's book, "First Aid to the Injured" give much information. Why not make a selection from Gray's Anatomy if more detail is required?

H P G and I A A—We have seen the advertising Christmas cards already They were in circulation, we have been informed, before the improper use of our notice was brought to the knowledge of the company,

Scalpel.—We recommend "A Dictionary of Medicine," by *Dr G M* Gould published in England by Messrs Baillière, Tindall, and Cox, King William street, W C

Viator, whose question we answered last week, has sent some stamps which we desire to return to him, but we have mislaid his address.

Public Vaccinator—Yes A sterilised needle or lancet blade is used by some operators and a special instrument by others

Mr F. B. Diver's communication escaped acknowledgment. The paper will be inserted

A Registered Medical Practitioner is thanked for his communication.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Valedictory Address

ON

OPINION THE SALT OF FACT.

Delivered before the Harveian Society on Jan. 19th, 1899,

BY JAMES F. GOODHART, M.D. ABERD.,
F.R.C.P. LOND.,
PRESIDENT OF THE HARVEIAN SOCIETY.

GENTLEMEN,—When I accepted the honour of becoming your President I had thought from what I had heard that the Harveian was one of those nice "you-need-not-dress-for-dinner" sort of societies that allows its retiring officers to disappear by a euthanasia of music and tobacco unheard of and unsung. But when not long ago I unearthed my copy of the laws of our society I found to my discomfort that a part of your President's *duty* was to give a retiring address. I had, however, been reading Keats and I took happiness from the thought that he had said: "It appears to me that any man may, like the spider, spin from his own inwards his own airy citadel. The points of leaves and *twigs on which the spider begins* her work are few and she fills the air with a beautiful circuiting." The points of leaves and twigs on which I begin my work are decidedly few. I find them stated thus in our laws: "At the annual meeting in January the President shall deliver an address on the objects of the society and the best means of accomplishing them." Never have I read a sentence which filled me with more blank dismay. Its uncompromising decision leaves no opening for strategy. Front and flank seem equally impregnable. But as I sat in the plenitude of my despair this thought came to me: that a society which has reached its sixty-eighth session has already found out its objects and also the best means of accomplishing them, and that I may therefore reconnoitre the past perhaps to more purpose than prospect the future. And this is what I have decided to do.

It is often said in societies of this kind that our object is to obtain facts and not opinions. But, as it happens, I am very fond of opinions, without in the least wishing to decry the more positive value of facts. From my present point of view a fact is dead. While of opinion I would contend, as has been finely said, that promise touches us as finished success can never do. At any rate, as I have sat here listening to the papers which have been read before the society during the year, many have been the interesting points which have crowded into my mind as this reader and that has touched upon the promise of the future. Take the first paper that occupied us by Mr. Mansell Moullin—the Treatment of Malignant Growths by Toxins. It was a most interesting paper, but even so it was so most of all by what it suggested.

I remember that five-and-twenty years ago there was a discussion on Cancer at the Pathological Society[1] which resolved itself into a discussion on, Was it a constitutional or local disease?—did it come, that is to say, from *something* in the individual or from something absolutely in the part itself and outside him? Sir James Paget maintaining that it was a constitutional disease relied much on the argument that its recurrence after complete excision is almost constant or that not more than once in 500 cases does it fail to recur. Sir James Paget very justly says: "Suppose a man to have performed 500 vivisections to determine *such a point as this*—whether a certain mass within the body is altogether local or for the most part constitutional—and suppose he has found that after 500 vivisections he has got but one single exception to the rule that the growth re-appears after removal, he would be a bold man if he repeated his vivisections—he would surely be content with his results." Yes, it is absolutely certain that force is no *remedy for* malignant growths and yet twenty-five years have gone by and we are still as busy as ever removing cancers and ever and ever more early and more completely and still the experiment fails. And so shall we continue to do, for hope springs eternal in the human breast and the enthusiasm of surgery must never be damped by the recognition of defeat. Youthful surgery sins, not by omission; but surgery (not surgeons mind) grey-haired and old would leave us poor indeed.

Yes, we still go on removing cancers, but, as Dr. Moxon said in the same discussion, constitutional and local are not antagonistic terms; and this—although I daresay not in his sense—I have always held myself. I certainly cannot conceive that if a disease be purely local that it could fail to be completely eradicated in a definite proportion of cases, to take the one argument alone, for one cannot do more than touch upon such a question here; and yet there can be no doubt that the disease does begin locally and generalises from the local swelling and therefore I myself should certainly always be an advocate for attempts at a local cure. But I am equally unable to believe that the local element is so absolutely local as a foreign germ would make it or that excision will ever prove alone its cure. I have always thought that a something must be inherited that allows of an irregular distribution or *correlation* of energy between one part and another and that thus growth becomes substituted for function; and no doubt this is no sudden thing; it is a slow process of evolution in the cell elements of this part or of that—and thus I can understand why the surgeon fails to attain his aim. The longer I live the more I become impressed with the reality of an hereditary proclivity to cancer and so thinking it appears to me that whatever local treatment is suggested should deal not only, perhaps not so much, with the complete excision of the *disease as with those unnatural explosions* of energy which bring about the malady.

Thus I think that there have been of late years three distinctly promising and rational methods of treatment proposed. I wish I could add that they had proved to be successful. Some time ago my friend Dr. Inglis Parsons read a paper before this society on the Treatment of Malignant Growths by Currents of High Electrical Energy; he went into the matter in a thoroughly scientific and philosophic manner. And he believed that he might by this means produce some widespread modification of the nutrition of the part and thus make the disease wither. He demonstrated, indeed, that organic tissue can be disintegrated by currents at high pressure, but they failed, as Dr. Inglis Parsons thinks, because of the different resistance offered to the current by the *diseased and healthy tissues through* which the needles pass. I believe this to have been, nevertheless, a distinctly rational and promising hazard. So also seems the proposal under certain circumstances for the removal of organs that condition, or at any rate are associated with, the function of the diseased part—the ovary for cancer of the mamma and the testis in cancer of the prostate—of which we heard something at the reading of the paper that has formed the text of these remarks. This also fulfils my idea of a natural method of attacking cancer and it is possible that it fails just where so many methods of treatment fail in medicine and surgery, because in our anxiety to be neither too soon (that is, meddlesome) nor yet too late one is unable to act early enough. But there must be many cases where the growth is not subject to any known *controlling* power or has no known correlative—cancer of the intestines, for instance—and therefore from one cause or another, at any rate, these measures fail or are inapplicable. For such it is rational, although desperate, to hit out all round so to speak and this has been attempted by the use of a virulent erysipelas toxin. I am afraid so far, as Mr. Mansell Moullin's lucid *résumé* of the history of this method told us, that the procedure as practised with virulent toxin is doomed to a similar fate as its predecessors. It is certainly a measure I should hesitate to advise, the risk appears to be so considerable. And yet may there not be in the idea a stepping-stone to more perfect things? At any rate, I seem to see in it that intuitive feeling after truth which was perhaps expressed in times gone by in the belief that the animal economy does not readily allow two masterful diseases to run concurrently. And surely there is a good deal in this. I see many a one who is asthmatic whose great dread is that of weak lungs—meaning consumption. People do not think nearly so badly of asthma and it consequently conveys a good deal of comfort to a man's mind to be assured—as I believe in the truth of this old doctrine—that his future risks are not those of the consumptive. This was, of course, taught years ago by Rokitansky, but I have heard it [illegible] late. All the same I think it is largely [illegible] an [illegible] the asthmatic never becomes

No. 3935

occurrence is rare; and given a case of heart disease which involves more or less pulmonary stasis, or pure spasmodic asthma, or primary bronchitis and emphysema, the chances are decidedly against that person having anything of the nature of consumption.

Then how seldom it is that two specific fevers run together. One may sneak in when some other has left the door open, but two together—no. Again, I know an old gentleman who was apparently incessantly and incurably giddy. At any rate, his trouble was of years' standing and he had long given up all hope of relief by drugs; he had tried too many without avail. He had a very severe attack of double pneumonia which all but cost him his life and he lost his vertigo and it has not returned. The old theory of counter-irritation was based, I suppose, upon some such idea. Years ago it used to be the practice (perhaps it is now) to rub the surface of buboes vigorously with stick nitrate of silver; the counter-irritation of joints is certainly still current practice. How do these act? Is it not that the local conditions called into play by the traumatic inflammation are antagonistic to the free play of the pre-existing disease and this in several ways that it would be tedious to mention? And in cancers, I take it, to cure them we have to alter in some way the local conditions which gave rise to the exuberant growth of the cells. (And, by the way, are cancers always the same? Is the cancer which breaks out in A the same vitally and physiologically as the like histological structure when it occurs in B?) It is very rare indeed to find two separate primary sources of malignant disease in the body. I have once or twice seen cancer of the breast and cancer of the stomach but the occurrence is a curisity. One has therefore to attack some local inveteracy. And the injecting virulent erysipelas toxin might well, I think, exercise a sort of Star Chamber influence upon any such revolutionary quarter if only it could be made to distinguish between the righteous and the wicked. This attribute of selectiveness is what we want and which is so difficult to find.

Another paper which raised a very interesting question was that of Dr. Armstrong on Dilatation of the Stomach. I will not, however, dwell long on this point as I have elsewhere said something already on the matter. The subject was treated of in the paper and discussed both ably and temperately. But I cannot help saying that outside our society I hear talk of dilatation of the stomach much more often than it seems to me to occur. What is common is what now goes by the name of proptosis, and which is a condition that in the great majority of cases does not call for treatment, for it causes no symptoms. For take, say, 100 people, and examine them one after the other at varying times after their morning meal. I venture to say that you will find at least several amongst them who will as late as 12 or 12.30 give to physical examination a splashing stomach coming more or less to the umbilicus, sometimes lower. And yet they will complain of no gastric symptoms whatever. They may not be the robustest of mankind—they will probably be nervous or used up in some way. But they are not cases of gastric disease. Gastric catarrh is the term I find often applied to these cases, but I look upon catarrh as a very dangerous word. It has a likeness to golf in that when once you take to it you become its slave. Perhaps I ought to explain that as regards golf this is not a fact observed by myself, but one stated to me by others, and the Lunacy Commissioners, you will remember, never allow anyone to be deprived of his liberty of action on this class of evidence. So the golfers amongst us need not take up their clubs against me.

I must confess to being unable for the most part to admit the existence of disease that shows no symptoms. Proptosed stomachs and the *fin-de-siècle* dilatation of the heart which one hears so much about from the general public will not live in the nomenclature of disease for that very reason. Dilatation of the stomach and dilatation of the heart are very serious diseases, but they give definite symptoms which suggest their seriousness. But I am not exaggerating one whit when I say that at the present day I am frequently seeing people who are frightened out of their very lives by fear that they have dilated heart when that organ is perfectly well able to take care of itself.

There is a saying, I believe, that a properly regulated domestic establishment should have its own laundry, and therefore as we are all very sweetly sociable here to-night we will do a little washing by making amongst us this whispering confession, that medicine, because it is so noble a profession, is terribly prone to be run away with by a fad. It is impossible to have a right judgment in all things and we are so anxious to cure our patients that we go "tally ho'ing" after many a false scent, and I fancy that if the history of medicine be written in anything less perishable than the sands of time that by-and-by it will stand recorded that stomachs and hearts (possibly duodenums also) furnish conspicuous evidence of the fact. But I have linked these two—heart and stomach—together for the purpose of saying that in the case of each I believe there is a dilatation which runs a parallel course and the course is not what is usually taught. It is commonly held, and of course there is much ground for holding, that the dilatation of each is due to the inefficiency of the muscular walls to drive the contents through narrow orifices; that the work being too much, hypertrophy of the muscle is brought about, and that not being enough the walls of the cavity dilate. Dilatation is the *cause* therefore not the *result* of an hypertrophy which has shot its bolt and failed. In the case of the stomach it is assumed that the pylorus is strictured or kinked or displaced in some way so as to produce an obstruction. I doubt whether there is any evidence sufficient to prove this in the majority of cases. There are a certain number of cases of fibrous cancer of the pylorus in which it is so no doubt. There are, perhaps, a few cases—very few—where a fibrous thickening of the pylorus exists. But it is my strong conviction that this will not explain all the cases of true dilatation which are met with and that the real explanation of some is a primary, passive dilatation from chronic indigestion or defective innervation in the first place with hypertrophy as an attempt to remedy the evil in the second place. I believe a similar sequence of events may occur in the heart, and therefore although I have gently railed at, and think we ought to be very careful to avoid, taking illiberal views of the vital capacity and resistance of our organs, muscular or other, to avoid being morbid in our estimates of what is disease, I yet think that we must be careful in the matter of dilatation of important muscular cavities not to rush to the other extreme and regard as nothing what may be early evidences of serious organic change.

And now to one other point. I was very much interested to hear Dr. Sidney Phillips (in his paper on *the Treatment of Typhoid Fever*) give utterance to the opinion that that disease has changed its type. In the Harveian Lectures which I had the honour of delivering before the society in 1891 I ventured, notwithstanding the almost scorn with which such an idea had been received in Sir Thomas Watson's day, to affirm that diseases must change their type. I took then more especially the *a priori* argument that man is in large measure the product of his environment; that as that changes, as change it must, under the varying conditions compelled by his needs and his rapidly increasing progeny, so must disease change. And I have no doubt that that argument is sound. I attach very little weight to the usual reply that there is no evidence of change—the pneumonia of years gone by is the pneumonia of to-day, and so on—because the changes which occur are insensible. We live in—we are a part of—a general dissolving view. We change ourselves, but so insensibly that had we no means of seeing ourselves in looking-glasses and photographs we should complacently affirm that we were still the same as we were thirty, forty, or fifty years ago. And so we should continue to go on until, in fact, the day when the keepers of the house tremble, and the grinders cease because they are few, and those who look out of the windows be darkened, because man goeth to his long home. Nor do those in daily contact with us see any such glaring change as periodical photographs make ridiculously and painfully plain. The same we are, yet not the same. One may see this also in a more subtle manner by taking some of the novels of the past. Take "Tom Jones" or Miss Burney's "Evelina"—I may even come nearer down and say take even Dickens or Thackeray—and though you may delight in them each and all as giving an insight into the life of their day and generation as recording the play of human passion and emotion common to every age there is much in them which is quite uncongenial and out of touch with the feeling and the interests of the present time. I think it is the same with many old pictures. I go and see the Rembrandts at Burlington House and hear men say, "Ah, we cannot paint like that now." And then I hear that the art of making pigments is lost or that the world's virility in forging genius flags, and that great painters, great poets, great anything, are all of the past. I do not believe a word of it. The explanation to my mind lies in this: that we live in another world altogether, born and bred under altogether different ideas, different schooling of light and shade. The great painters of the past painted their day—they could paint no other—and our painters paint their day—they can do naught else. It is impossible to step across the ages. No plagiarism—if I may so speak of Shakespeare, or Swift, or Fielding, or Burney, or Dickens, or Thackeray—can ever be written, and if it could it would appeal to ears unfitted to receive it and appeal in vain. Two distant periods can never be other than contrasts.

I stood but yesterday on the edge of cliffs where I knew the sea to be advancing and the coast line to be slowly altering in response. But what could I, the wastrel of a moment, see of the change as it passed? Practically nothing. The coarse outlines must long continue apparently the same—it is the fine details that the insensible alterations of its environment must necessarily work upon and modify.

> "But we that are not all,
> As parts can see but parts, now this, now that,
> And live perforce from thought to thought, and make
> The act a phantom of succession."

If in the course of years even our very thought changes all our modes of expressing thought will change too, and language and painting and so forth are evidences thereto. And if so, shall disease, which also, alas, is one of the languages of nature, fail in this? It cannot be.

But with disease it is most difficult to show the contrast because, as I have said, it grows up with us, moulds itself insensibly to our shape, changes insensibly as we change, and thus the pneumonia of a day gone by seems to be very like the pneumonia that we have to deal with now. Then, too, we cannot see the past, and it is so difficult to describe disease. Very few people indeed have the power to do it, and thus the records left behind are very different from the experience of the man who actually handled the disease. So it was, and so it is. What would we not give to have the whole experience, say, of men like Gull and Jenner laid bare before us? Why, the miracle of the loaves and fishes would be shown to be possible even now—for I venture to maintain that there would be many basketfuls of crumbs of insight into disease which would remain over and above the five loaves and two fishes of broad outline with which for the moment we should satisfy our hunger—insights into diseases, many of which in all probability the possessors of the experience had not themselves obtained, but which other minds would light upon with a swift certainty of penetration. But these are all lost to us. But as evidence in favour of change, see what we have done for disease, to mention only a few of many facts. When I was engaged in making necropsies at Guy's Hospital, say, from 1873 to 1883, there was no disease commoner than pyæmia. Such cases would turn up day after day, sometimes two or three in a day. Some operation had been performed, suppuration had occurred in the wound, the veins therefore contained pus, and the lungs of the patient were riddled with abscesses. That disease, of which I have somewhere a large bundle of notes of cases, is practically expunged from our nosology and the medical student of to-day I daresay has never seen such a case.

Typhus fever is another disease that is practically a thing of the past. The last epidemic of the disease in London of any note was in 1869, thirty years ago, when I was house physician at Guy's Hospital. The diseases which may at any rate react prejudicially on the human economy and thus favour the attack of other maladies are being done away with; towns and houses are being made more healthy, the preparation of food is more carefully superintended, living is made more easy to the lower classes, relaxation and recreation are being taken in larger proportions. Surely all these things, by bracing up the health of the subject, must tend to modify the reactions of disease by increasing the resistance to their natural course and even to their very inception. By boiling our water and milk and looking after our sewerage we are doing something to starve the typhoid bacillis of its food. Sir A. Lawes, by doing away with the rotation of crops and cultivating turnips in one field year after year without manure, was enabled to reduce his turnips to radishes, so far as size went. Is there any reason to doubt that the same sort of modification will happen in the case of the starved bacillus of typhoid fever, and if so what would that be but a modification or change of type? I agree *in toto* with what Dr. Sidney Phillips said to us that "typhoid fever tends to vary with the conditions associated with its origin and though such variations are slight individually and gradual in evidence in their sum they suffice in time to produce a considerable modification of the original disease. There is considerable difference in the symptoms described fifty or even twenty-five years ago and those occurring to-day. The difference is marked in the lessened severity of the abdominal symptoms; the tongue is now often moist throughout the disease instead of dry and baked; tympanites and diarrhœa are much less pronounced; probably also hæmorrhage and perforation are less common; tremors and dilatation of pupils are now uncommon; and instead of noisy, active delirium the mind is often clear throughout even fatal cases. The typhoid state with the patient sunk deep in bed, unable to move himself and unconscious or semi-conscious for days, is now quite exceptional; relapses are less frequent, and yet the mortality is not lessened." Dr. Phillips attributes this "to a lessened tendency to ulceration of the intestines, and argues that if so much variation of type has taken place in a quarter of a century, much more has gone on in fifty years, and that where conditions existed such as made typhus rife the distinctive features of typhoid may well have been affected, and that in this is possibly to be found the explanation that the separate diseases were regarded as one."[2]

There are other diseases which change their type perhaps by exhausting the soil by immunisation or otherwise, and of this class I must mention scarlet fever. I seldom see a case of scarlet fever now of anything like the severity which occurred often thirty years ago; I am by no means sure that it has been as frequent of late as it used to be, but I will not make much of that, because epidemic diseases have a trick of lying dormant for a time and recrudescing. But as regards severity I have made a point of inquiring in the last few months of many medical men, and all have without any qualification agreed with me that for the most part it is now quite a mild disease. This may be because, as in typhoid fever, pyæmia, and so forth, we are preventing the disease by boiling our milk and water and isolating the cases as they occur. But in such a widely distributed disease as this has been for now many years, and a disease, moreover, that in various grades of severity yet seems even in the mildest form to have the power of protecting the subject from future attacks, it is possible that a large proportion of the population is now partially immune and that in this way the disease has gradually been undergoing modification towards its ultimate disappearance. I would even take diphtheria as some evidence of the same tendency to transition. Now diphtheria is much more widely spread than it used to be and I do not know that one can say that it is less deadly, but I am much inclined to think one can say this, that its type is not exactly the same as it was years ago. Putrid sore-throat seems to me the term that best characterised the disease then, membranous pharyngitis and laryngitis that which best applies to it now. These carrion throats which one used to see are, I think, seldom met with now, and while there may possibly be more inveteracy about the formation of membrane there is yet, if I may so speak, evidently now something of indolence in the process. And now, in addition to any modifying influence of slow operation such as I speak of, we have the common resort on all sides to antitoxin; this, again, in greatly increased measure, if it sustains its reputation, as it seems likely to do, must work in the same direction.

Well, then, of course no one can talk nowadays of any disease without dragging in gout. He is a capital guest at every party, he has so much conversation in him. So I do not like to leave it out. And, indeed, I cannot but think that gout is a witness also to my theory of to-night. And in this direction—that whereas true gout of the foot or hand is surely less common than it used to be as a disease it appears to have become distributed and now appears in this one and in that in a number of minor ailments. Gouty dyspepsia, gouty bronchitis, and tracheitis, gouty nodulations about the phalanges, gouty affections of the skin, gouty pains here and there, and so on. It may well be discussed whether many of these ailments are really what they are supposed to be, but a common consensus assigns them indubitably to gout and if so I think we may fairly say that from some cause or other the disease is undergoing modification and is now distributed in such a manner as to make it often not easy to distinguish. It appears, in fact, to be undergoing in the body social a similar modification to what it is known to undergo in the body individual, for it needs no saying here that as gout grows old in the individual so it loses its explosive character and is replaced by something that wanders fitfully from one part to another and is less easily controlled by the treatment that once was successful.

---

[2] Abstract from Paper on the Treatment of Typhoid Fever, by Dr. Sidney Phillips, Brit. Med. Jour., Nov. 12th, 1898.

A good deal of point, with reference to change of type, was made in former times of pneumonia, some holding that it proved the case against change of type, others that it did exactly the opposite. I incline to throw in my lot with those, if there be any such, who think that the disease is slowly changing and in the direction in which of old it was contended that it was changing—viz., by being less violent in its attack. Pneumonia is a very common disease, but it is not common to see those furious outbursts which I think I saw more often twenty years ago. I very seldom see now those few days of acute pyrexia and the sudden crisis and the patient is well. It has become a disease which drags on ten or twelve days or more, is more inclined to spread from one part of the lung to others in an insidious way, and then, too, is it not now more prone to produce empyema than it used to do? Mind, I am not stating these thing as facts. I am avowedly giving you only my own impressions. I am making it my business to set you thinking, because, as I have said, this is one of the main objects of our society. But we know more of pneumonia than we used to do; we know now that it is associated with the growth of the pneumococcus. And we also know that there is many an empyema which appears to be only an empyema that contains the same organisms in the fluid. We know a further fact which seems to me to be of importance. Pneumonia is a very common associate or result of influenza and I have had the expectoration examined in several of these cases in the expectation of finding the special influenza bacillus, but no, the report has always been that the pneumococcus was present. So has it been in influenzal empyema. Now there can be no doubt, I suppose, that the pneumonia associated with influenza is a peculiar one. We all know how often it creeps about the lungs and will not clear up and there is no crisis, yet it is associated with just the same micro-organism as what I may perhaps call the old-fashioned croupous pneumonia. This seems to me to be a bit of evidence which goes to show that acute pneumonia is modified by its reaction with other diseases, that it is indebted to the open door left by influenza—and if by one disease why not by others?—for some of its power for harm, and that therefore by the increase in our knowledge and the more thorough application of hygienic measures a further attenuation or destruction of its influence may be compassed.

I have only time to mention one other disease and that shall be appendicitis which in my opinion has become an appallingly common disease of late years. Now this again is an *obiter dictum*. I am unable to give much proof but thinking matters over as dispassionately as I can I cannot think that it was met with years ago in anything like the frequency that it is met with now. I know, of course, that it will be said that it passed unrecognised and that it is like many another disease: when we begin to look for it we find it much more often than we supposed. But I cannot admit this so well for appendicitis as I could for many another disease. Because it is such a serious malady attended with acute symptoms and, moreover, it is a disease which was well known and recognised certainly before I entered the profession of medicine. I cannot think that within my time the disease has been smuggled away as simple peritonitis or tuberculous peritonitis. And I believe that for some reason or other it has increased in frequency. There is no reason why it should not. Diphtheria has increased in frequency. But there is the greatest possible difficulty in assigning any cause to the fact. Perhaps a new bacillus has cropped up, but I have my doubts. I do not see why the bacillus coli communis which is supposed to be the organism at fault should be new; it seems a very natural inhabitant of the part affected. It would be a strange thing if the colon were not the home of all sorts of bacilli, notwithstanding what tends to be, I think, one of the fads of the present day—that by giving a little β-naphthol, or salol, or creasote, or one of the fifty other "intestinal antiseptics," you can keep the colon as sweet, say, as the stomach. I am a great believer in the colon. It is a great absorbing organ As long as food is in the small intestine it is fluid—never solid—directly it passes into the colon it becomes solid. That can only mean that absorption goes on vigorously in the large intestine and I am in consequence an ardent opponent of people scouring themselves out with daily pills and potions. But if it is a great absorber it is also the main sewer. There is much in it which is cast out into the draught and which no antiseptic does much to clean. Nevertheless, it will lock up its contents in many a one for several days together and that with the smallest appreciable ill effects. This is not to be considered as an advocacy of constipation, it is only a passing caution in this day of ptomaines, antitoxins, and intestinal antiseptics—ideas which are all of them good in their place—that an ideal pathology or pharmacology may easily be made to outrun wisdom and common-sense.

To return to appendicitis, if it is more common than it used to be the reason is at present veiled—but the increased frequency of a disease may be said in some degree to be a variation of that disease inasmuch as it gains a firmer hold upon the community—and in so doing tends, one may suppose, to become by cultivation either of greater severity or to wear itself out like ringworm on the skin or as I suppose scarlet fever to be doing by gradually using up the available soil.

But I must draw to a close. Before doing so let me give one instance which may at first sight seem to weaken the argument for change of type in disease. That instance shall be influenza. I need not go into what our experience of influenza has been during the last few years. We are only too painfully familiar with it. But let me read you an extract from the pen of Huxham of Plymouth in 1733.[3] "On Feb. 10th some were suddenly seized; the day after they fell down in multitudes and on the 18th or 20th of March scarce anyone had escaped it. It began with slight shivering, followed by transient heats, headache, violent sneezing, flying pains in the back and chest, violent cough, and a running of thin sharp mucus from the nose and mouth. A slight fever followed, with the pulse quick but not hard or tense. Several had racking pain in the head, many had singing in the ears and pain in the meatus auditorium, also sometimes an abscess formed; exacerbations and swelling of the fauces were likewise very common. The sick were in general much given to sweating, which when it broke out of its own accord and was very plentiful, continuing without striking in again, did often in the space of two or three days carry off the fever. The disorder in other cases terminated with a discharge of bilious matter by stool. It was rarely fatal, and then mostly in infants and old worn-out people. Generally it went off about the fourth day, leaving a troublesome cough often of long duration and such dejection of strength as one would hardly have suspected from the shortness of the time. The cough was in all very vehement, hardly to be subdued by anodynes, and it was so protracted in some as to throw them into a consumption." In another place the same writer talks of the tongue looking as if rubbed with cream, large spitting, a sudden, nay a profuse, diarrhœa, with violent griping, &c. Few would fail to see in this description—Huxham appears to have been one who could describe what he saw—the very disease which has been with us on and off since 1889. But even here there is one important difference, for it is said to have been seldom fatal.

Measles, again, is another disease which does not appear to have altered much; the description given by Sydenham in 1670 would read exactly for the disease now. It has varied in intensity from time to time as all epidemics are wont to do. But, then, of these two diseases I think it may be justly said that they are of more epidemic type—influenza certainly is—and diseases which come and go, particularly those which reappear only at considerable intervals, have less chance of modifying their type by the continual friction of their environment; thus in their recurrence they drop into more or less virgin soil and run their natural course unhindered. Then, too, both these diseases have much in them that is common to a feverish cold, and colds are proverbial for the way in which they victimise repeatedly the soil that suits them; apparently they are turnips which would never become radishes. There are those amongst us who never "catch" them. Would that those who do so might "catch" instead the hidden secret of their success. But for a large proportion of humanity, I take it, they are of the minor ills we suffer, of those of which we stand most in dread. Nothing seems to stop them; they attack us again and again, and indeed it may almost be said of them that the more we have the more we may And this would certainly appear to be true of influenza We have all come across many people who having had influenza some years ago have had repeated attacks of something like it ever since It is said that the recurrent attacks are not true influenza, but it is really very difficult to say in some of these cases in what the results differ from the cause Moreover, in both these diseases it is very difficult to say what is the disease, for both, it is clear, make an open door for the entrance of the pneumococcus, the bacillus tuberculosis, the streptococcus, and so on

---

[3] Creighton's History of Epidemics.

There are many other points on which I had wished to have touched in the many excellent papers which have been brought before us In the paper on Functional Dysphagia, by Dr StClair Thomson, why is it that dysphagia so nearly always bespeaks a cancerous stricture? Here is another of those points in muscular pathology which is not without its suggestiveness in relation to stricture obstruction and muscular failure elsewhere There is the paper on the Subsequent History of Adhesions in Joints, the Peritoneum, and Elsewhere, by Mr Marsh, which could not fail to touch on many a moot point in pathology and treatment, for the serous and synovial membranes are of the most interesting of all our parts they are at once so constitutional and so local But time fails me What I have said has been very crude, I have been away from books These remarks are also very topsy turvy, but then that is not altogether inappropriate for I have turned things somewhat upside down by my contention that opinion is the salt of fact But is it not so? Solid observation must ever be the main object and the basis of the work of a society like this, but around it there is a legitimate sphere of influence for that stimulating if nebulous atmosphere of thought which sometimes enables the poetic insight of the genius to piece discovery together.

> 'Maybe wildest dreams
> Are but the needful prelude of the truth'

Turning now more particularly to our society and its doings, I was about to say that we have had an uneventful year, but from the point of view which I have taken in my address I must not say—I will not say—that it is so, for, indeed, any paper to which honest thought and work has been given cannot be other than an event and any one of those to which we have listened may contain the germ of an epoch even although as yet we see it not. But in another respect our annals have been sadly eventful, for some of our great ones have fallen during the year Our honorary members are limited to 12, and of these no less than 4—Dr Cleveland Dr Hare, Sir William Jenner, and Sir Richard Quain—have all left the Land of Promise and have entered the great Continent of Fulfilment Surely one may say of all of them, so far at all events as our small medical world is concerned, "They sleep with the enduring dead"

A Lecture

ON

MEDICAL LONDON.

Delivered at the South place Institute

BY E BAXTER FORMAN, MD BRUX, M.R.C.P. LOND, MRCS ENG, L.C.C, J.P.

LADIES AND GENTLEMEN —I am indebted to your honorary secretary, Mr Shoewring, for the admirable title of this lecture. I shall not be far wrong in assuming that what is meant by it is, What are the public medical services? how is London governed from the medical side? I propose to speak in detail on some parts of the subject but only to glance at others. Poor law administration and sanitary administration seem the natural divisions into which the subject falls, but there are *some* duties which do not come under either head First as regards Poor law administration It is controlled by the Local Government Board and partly carried out by the guardians, partly by the Metropolitan Asylums Board, and partly by the London County Council The sick poor are attended by a district medical officer elected by the guardians in virtue of orders issued by the Local Government Board which defines his duties An important reform of late years is that the guardians supply the medicines which are compounded by their own dispenser For some time the guardians have had the power of providing hospital accommodation and nothing in the treatment of the sick poor shows so much advance as the provision of the new Poor law infirmaries. There are now 24 of them with 12,000 beds While of old the workhouse sick wards were filled with the infirm and the incurable the new parish hospitals treat all non infectious diseases They are built according to modern ideas, they are liberally equipped, and the skill of the medical staff and the training of the nurses leave nothing to be desired These institutions do not supply all the wants of the sick *poor of London* In all continental cities, though there are *small charitable institutions* the great hospitals are aided either by the state *or* by the municipality Here as you know it is different and it is our boast that these noble institutions are supported *entirely* by voluntary subscriptions They open their doors as freely and as eagerly as if they were paid for the generous duties which they perform They are the most democratic of institutions, for they enable the poorest and the richest (*more* than the class between) to benefit by the same skill In 1897 there were 91 hospitals with 7234 beds in daily occupation, 99,178 out-patients were seen, and 1448 persons were received as *in patients* The *medical staff numbered* 1055 and the nursing staff was 2660, while the income was £690,006

THE CERTIFYING OF PAUPER LUNATICS

Perhaps the most important duty of the district medical officer is the certifying of pauper lunatics The supposed lunatic may be brought before the medical officer as an ordinary parish patient; or the relieving officer whose attention has been called to the case by the friends may bring him into the workhouse for examination, or the police may have arrested him while wandering about the streets Anyway, a magistrate must examine the supposed lunatic with a medical officer If he is found not to be insane he is discharged to his friends If his case is doubtful and if it is thought he may recover very quickly he is legally detained in the workhouse for fourteen days; if, however, there is no doubt about his case he is certified as a person of unsound mind and is sent to one of the county asylums Now the guardians lose him and he passes under the care of the London County Council Admitted to the asylum he is examined and notes are taken of his symptoms and history by one of the medical officers and a little later he is visited by some members of the managing committee of the asylum who are necessarily members of the Council During his stay he will be seen by members of the committee and certainly at the statutory inspections, and any complaint which he makes or any grievance which he alleges is duly investigated *Even here his* protectors are not exhausted Periodical visits are made to him by the guardians of his parish and more important still are the visits of the Commissioners of Lunacy The Commissioners are a body of six experts, three of whom are medical men and three are lawyers The total number of lunatics and imbeciles chargeable to the parishes and unions in the County of London on Jan 1st, 1898, who were in asylums, licensed houses imbecile asylums, workhouses, and with relatives was 20 482, against 16,358, ten years ago On Jan 1st, 1898 the accommodation in our own county asylums was 11,777 beds, against 7725 ten years ago The increased accommodation includes extensions at Cane Hill and at Claybury and temporary buildings at Banstead and at Colney Hatch Lately we have *opened some* temporary buildings at Hanwell At Bexley Heath Asylum *accommodation for 2000 patients* is *fast* approaching completion, it has indeed, already admitted a number of chronic patients Horton temporary buildings for 700 patients will be ready in a few months, while the permanent asylum *there will be ready in two years* The guardians pay the Council 9*s* 11*d* a week for the maintenance of each person I may add that the cost of the maintenance of the lunatics to the Council is just under half a million a year *By a very odd arrangement the London County* Council has nothing to do with the imbeciles or harmless lunatics, as they fall to the lot of another body which I shall describe directly, the Metropolitan Asylums Board Claybury Asylum commenced by the magistrates and finished by the Council, cost nearly three q[illegible] of a million pounds It is unlikely, [illegible] asylum will be so expensive. The Council is doing its best to overtake the requirements of London and is proceeding in its work with care and circumspection. It has got the gigantic task now well in hand and soon it will be no longer necessary to go outside our own asylums for the housing of our lunatics. We may, however, look to having to provide for 600 additional cases every year. You may ask what has rendered this great increase of accommodation necessary? Well, there are many subsidiary causes, such as lessened death-rate, &c., but the great cause is the increase of population. Is insanity, you may ask, really on the increase? It is to a small extent in London. The greatest causes of insanity are drink and heredity. Nay, often the drinker has inherited some weakness of will, some mental instability, for even alcohol will not drive everybody mad. Alcohol sifts out the susceptibles who if they miss the grave of the suicide march straight to the wards of an asylum. But do not let the man who is able to carry his liquor without showing it think he will escape. Retribution limps after the topers who remain and slowly but surely overtakes them at last, and our hospitals bear witness to physical maladies which are equally the result of intemperance. It may not be out of place to say that we do not stand still in the treatment of insanity. From the continent of Europe, from the United States of America, we are seeking to learn anything which can be taught us. We are employing the highest skill in trying to elucidate the dark problems of mind disease and whatever we find to be best either in the construction of the buildings or the treatment of the unhappy inmates will be adopted.

VACCINATION.

Another duty of the Poor-law medical service is the performance of vaccination. It would be better if it were in the hands of the central rather than the local authority. Lately the public *mind* has been *much* exercised on this subject. A powerful Government introduced an admirable Bill, but finally made such concessions that what at last passed into law was only the emasculated form of what was originally proposed. The Royal College of Physicians of London at their meeting just before the Act was passed said that, "Having learnt that certain changes are likely to be made in the law relating to vaccination we think it is our duty to reiterate our conviction that vaccination properly performed and duly repeated is the only known preventive of small-pox." The Royal College of Surgeons of England about the same date reported: "We, the Council of the Royal College of Surgeons of England, desire to put on record our opinion of the value of vaccination as a protection against small-pox. We consider the evidence in favour of its life-saving power to be overwhelming and we believe from evidence equally strong that the dangers incidental to the operation when properly performed are infinitesimal. Experience has satisfied us that even when vaccination fails to give complete exemption from small-pox it so moderates the severity of the disease as not *only to greatly reduce* the mortality but to lessen the frequency of blindness, disfigurement, and other grave injuries. We would therefore regard as a national calamity any alteration in the law which now makes vaccination compulsory. We are, moreover, firmly convinced that revaccination is *an additional* safeguard and should be universally practised." A Royal Commission after sitting for seven years reported unequivocally by a majority of 11 to 2 in favour of vaccination. They say that they found vaccination a valuable preventive of small-pox, that the process could *not* be safely abandoned and replaced by other precautions, and that while some of the alleged dangers are real they are in truth unimportant in relation to the extent of vaccination work done and are diminishing under the better precautions of the present day. Yet in spite of this, in the very *land of* Jenner the new Vaccination Act lets even modified compulsion give way before the conscientious objector and revaccination is *not mentioned* at all. As the years go by we lose with the ardour the enthusiasm of youth, the credulity, the faith in the virtues *of many* things, but yet after thirty years spent in a wide field of observation and with now no interest to serve but that of promulgating what I believe to be right action I still believe in vaccination. What are the objections *to it*? 1. It is alleged that vaccination is inefficacious. Early *in* the century the decline in small-pox astonished the world, for nothing had been seen like it. It was not due to improved sanitation, for there was no sudden spreading of new ideas on this subject—it was due to vaccination. Mr. Holman Hunt the other day, in a letter to the *Times*, relates how in 1852 he had asked the then veteran judge, Mr. Stephen Lushington, his view of the relative beauty of ladies in the passing day and seventy years previously. The answer he got astonished him. "You can have no idea how it was that not more than one person in twenty then was undisfigured by small-pox and this generally to such an extent that whatever beauty there had been was seriously marred. It followed that when a woman escaped there was a disposition to regard her as a beauty for this cause alone and if, in addition, she had chiselled symmetrical features and good form of face and figure the admiration of her amounted to worship. The difference," he concluded, "I see now is that every woman we meet would have been a beauty in my early days." I inquired some years ago at one of our small-pox hospitals as to the mortality among its nurses and was told that *no nurse was* allowed to enter the service whom they could not sufficiently vaccinate, but that with that precaution no nurse had taken the disease. During thirty years the total number of boys who passed through the Bluecoat School was 5435 and only 1 of these had had small-pox. *After the epidemic* of 1871–75 it was decided to pass a general vaccination law for the whole of the new German Empire (I am quoting a book recently published by the Imperial Health Officer of Berlin and I may say I asked Professor Virchow about it the other day). Vaccination was strictly enforced under penalties on all infants and again at twelve years of age with the result that small-pox has practically been abolished in Germany ever since. Small outbreaks do occur from time to time, nearly all on the frontier, but the death-rate per million is almost *nil*, and in the army only one death has occurred since 1874 and that in an unsuccessfully revaccinated case. But no one can escape the law. 2. It is alleged that there is risk in the operation of vaccination, but if care is taken that no ailing child is vaccinated and the strictest antiseptic precautions are used with what should always be regarded as an important operation there is little fear of a bad arm from erysipelas or the like. A more serious danger is lest certain grave diseases may be introduced with the lymph, but our fears on this ground may be at once allayed, as it is no longer necessary to vaccinate from arm to arm as all danger is avoided by the use of glycerinated calf lymph. The calf is not liable to those diseases we most dread and glycerine has the power of killing disease germs from other sources. Before the new vaccine is used it is ascertained by the modern methods of bacteriology to be pure. It is curious that a healthy-born infant when nursed by a healthy mother is generally well for the *first three* months of life. Yet out of 568,907 deaths at all ages, 148,093, or about one-quarter, occur under one year of age. It is at the age of three months that vaccination has been usually performed and it has so received the blame for many ailments with which it could have no possible connexion. The new Act at least alters this. 3. Vaccination is, it is alleged, an interference with the liberty of the subject. The dictum of John Stuart Mill was that the only purpose for which power can be rightfully exercised over any member of a civilised community against his will was *in order* to prevent harm to others. Surely vaccination is a case in point. The great name of Gladstone was once the means of recommending the influence of authority in matters of opinion. Englishmen are apt to be governed by phrases and catchwords and too ready in every instance of a great *principle* to carry it to its logical conclusion, even to their own undoing. It is part of my duty to listen to summonses brought by school board officers against parents for not sending their children to school. A father will tell you that his son is sent to school but that he himself has to go to work and cannot tell whether the boy attends or not. A widow complains that she has to keep her eldest girl at home to mind the baby while she is out charing. The Education Act will have none of *such* excuses. It disregards the liberty of the subject and knows *nothing* of the "conscientious objector" and the result is that the magistrate must impose a fine. Up to now one-third of the children have escaped vaccination because the guardians fail to put the law into operation or because the magistrates refuse to convict. The best defence for the Government is that it was imperative that something should be done for the objector and that if they ceased to make martyrs they might get more converts. At present the new Act has brought little but ridicule. Next year a Revaccination Bill is promised and it is to be hoped that the common-sense of most people will avert the dire penalty which will otherwise be certainly enforced.

The Metropolitan Asylums Board.

The Metropolitan Asylums Board came into existence under Mr. Gathorne Hardy's Act. It is not a directly elected body. A few of its members are nominated by the Local Government Board, the rest being chosen by the guardians from among themselves. Perhaps the most curious thing about this Board is that it has not charge of the asylums except in the case of Darenth, Leavesden, and Caterham, which are reserved for imbeciles. I have already said that the care of the lunatics is the duty of the London County Council. At Darenth also the Board, a hospital-providing authority, has a school for imbecile pauper children. Another curious thing is that the Metropolitan Asylums Board has other schools, so that in this big London you have not only the London School Board, which would seem to be the proper authority, with its elementary schools, its higher grade schools, its evening continuation schools, its schools for the blind, and so on, but you have the London County Council with its schools, the parishes with their schools, and the Metropolitan Asylums Board with its school. Imagine the case of a street arab who has not benefited by the Education Act sufficiently to know the difference between *meum* and *tuum*. He may be sent to the London County Council's reformatory school at Feltham, to one of their industrial schools at Mayford, to the School Board ship *Shaftesbury*, or to their school for truants at Highbury; or he may be sent to a parish school such as that at Forest Gate or to the Metropolitan Asylums Board's school on the training-ship *Exmouth*. Surely there is some anomaly in all these school-providing authorities each supported out of the rates. The Gathorne Hardy Act allowed parishes to combine and so bring about a classification of paupers—that is to say, it allowed the infectious cases to be taken from the workhouses and infirmaries and placed in special hospitals by themselves. In 1889 the Metropolitan Asylums Board was made the recipient of all certificates under the Notification of Diseases Act with the duty of paying all the expenses which are incurred. Scarlet fever, diphtheria, typhoid fever, and typhus fever are the chief diseases mentioned in the Notification of Diseases Act and they must be notified in every case and a certificate sent by the medical man attending the sufferers to the medical officer of health of the district, and this must be done whether the patient is intended to be sent away from his home or not. The dealing with these infectious cases is, after all, the great work of the Metropolitan Asylums Board. During the year 1897 there were notified in the metropolis 45,417 cases of infectious disease. Of these 39,257 were legally eligible for admission into the Board's hospitals and out of that number 22,964, or 58 per cent., were actually admitted. It is a notable feature in the work of the Metropolitan Asylums Board that although they are legally responsible for the providing of hospital accommodation for persons suffering from infectious diseases chargeable to the guardians—in other words, for paupers—yet that with the approval of the Local Government Board they permit the admission free of charge of any person reasonably believed to be suffering from fever, from diphtheria, or from small-pox. Typhus fever, the disease of overcrowding and poverty, once so prevalent in London, seems almost to have disappeared; typhoid fever is admitted into general hospitals and is well under control; and small-pox for the time being is absent and has its own special hospitals. Measles and whooping-cough are not included in the notifiable diseases, so that scarlet fever and diphtheria are the two diseases which give the most trouble to the Metropolitan Asylums Board. Scarlet fever stands first. There were 22,848 cases of this disease notified last year. While the deaths from typhoid fever, thanks to sanitary measures, have fallen from 377 per 1,000,000 persons living in London in 1869 to 129 per 1,000,000 in 1897, diphtheria in spite of all our sanitation seems slowly increasing each year. 1899 showed 12,803 cases of this disease against 5870 in 1890. In scarlet fever to take the patient out of his insanitary surroundings and give him plenty of pure air will do something to help him, while with isolation and disinfection we may hope to limit the spread of the disease among the rest of the community. Against diphtheria we have now a weapon of great potency—the new serum or antitoxin treatment. When administered early in the disease its effects are marvellous and it has reduced the mortality of the disease by one-half. The medical officer of the London County Council shows by figures the great influence of school attendance on the spread of diphtheria. It rises during the term and falls during the holidays. Of the ambulance work of the Metropolitan Asylums Board its managers are justly proud. There is nothing so complete in Europe. In the year 1897 22,916 persons suffering from fever, diphtheria, and small-pox were conveyed to the various hospitals of the Board, 8941 convalescent patients were taken to the Northern and Gore Farm Hospitals, and 8917 recovered patients were brought back to London. Altogether 42,758 removals were effected by the land ambulance in 1897. In addition to this there were four steamboats forming a river ambulance, and these in the same year conveyed 1283 persons to and from the hospital ships at Long Reach. This ambulance service cost nearly £10,000. The Metropolitan Asylums Board has now eleven hospitals without counting the small-pox ships. The Grove Hospital, it is hoped, will be finished this year, and with the erection of the Southern Convalescent Hospital and some enlargement of the other existing hospital the Board will then have over 6000 beds for these infectious cases, not counting Gore Farm which with its 740 beds acts as a convalescent fever hospital when not wanted for small-pox convalescents. Though since 1887 the managers have practically doubled their accommodation for fever patients which has now, as their report asserts, reached a magnitude of which no one dreamed five years ago, it records for five years in succession the entire failure of the accommodation to meet all the demands made upon it during a season of the greatest pressure. In 1897 an important addition to the work of the Metropolitan Asylums Board was made by an order of the Local Government Board. The Board are now the authority for dealing with children chargeable to some parish in the metropolis when suffering from: (*a*) contagious diseases of the eye; (*b*) contagious diseases of the scalp (ringworm); (*c*) requiring either special treatment during convalescence or the benefit of open air; (*d*) who by reason of defect of intellect or physical infirmity cannot be properly treated in association with children in ordinary schools; and (*e*) who are ordered by two justices or a magistrate to be taken under the Industrial Schools Act to a workhouse or asylum of the district. St. Anne's House, Herne Bay, is used as a convalescent home and a site for an eye hospital has been secured at Brentford.

Ambulance Work.

Before I pass to the next branch of my subject I shall just notice the treatment of street accidents. There were 300 deaths from this cause last year. The police for the most part deal with sickness or accidents occurring in the public highway. They are almost invariably trained to give first aid to the injured, but should the case require treatment before the sufferer can be taken to a hospital the police surgeon is called in, or failing him the nearest medical man. If the police send for the surgeon payment is made from Scotland Yard. Sometimes in criminal cases it is necessary to send for a medical man and then if possible the police surgeon is called. This same official has to attend at the police station and dress the wounds of the accused or decide between intoxication or insensibility from disease. The police have ambulances of their own but there are two voluntary associations providing ambulance carriages for the streets. A gentleman who had organised an ambulance service for Paris came to me when I was chairman of the Public Health Committee and advocated a plan of horse ambulances for the streets with surgeons in constant attendance. As we manage our street traffic better than they do in Paris perhaps there is no necessity to imitate our neighbours in this respect. The physicians who advise the Home Office in cases of alleged insanity in criminals and give evidence in matters of medical jurisprudence, the surgeons in gaols, the medical officers of the Post Office, the medical officers of the army and navy, and the medical officers appointed by the London County Council to be called to common lodging houses in cases of suspected infectious diseases, and others do not come within the scope of this paper and I therefore pass on to the work of sanitary administration.

General Sanitary Works.

The work of the sanitarian interests all of us, for everyone is concerned in a movement the object of which is to prevent disease and to prolong life. There was a time when plague, pestilence, and famine were looked upon as Nature's means of getting rid of a surplus population whom it was difficult to feed and from the national [illegible] individual, something might be said for that view if epidemics only struck at the physically unfit, the insane, or the vicious; but with new ideas of heredity, with humaner views as to the sanctity of human life, we do our best to keep even the weakest alive and it is in this their environment that the sanitarian finds the field for his labours. With 4,500,000 people crowded together in the largest city the world has ever known we shall see what London has done to solve the problem before it. The first fact of vital statistics which strikes us is that the death-rate increases with the density of the population. In 1891 there were 829,765 persons living in tenements of four rooms or less. 37,055 persons lived 5 in a room, 17,232 persons lived 6 in a room, 5158 persons lived 7 in a room, 1844 persons lived 8 in a room, 83,580 persons lived 8 in two rooms, and 14,310 persons lived 9 in two rooms. Some time ago Professor Carnelly and others reported to the Royal Society as the results of numerous experiments "that as we pass from four-roomed and upwards to three-roomed, two-roomed, or one-roomed houses not only does the air become more and more impure as indicated by the increase of carbonic acid and organic matter, more especially in the micro-organisms, but there is a corresponding and similar increase in the death-rate with a marked lowering of the mean age at death; and that the rapid increase in the death-rate as we pass from four-roomed to one-roomed houses is by far most marked in children under five years of age. The death-rate among these young children in one-roomed houses is nearly four times that of children in four-roomed houses while the general death-rate is not quite twice as great."

The duty of keeping London healthy is divided between the London County Council, the Corporation of the City of London, the Thames Conservancy, the vestries, and the district boards. The cost of this process for one year according to the latest returns was £1,014,474, or 4s. 9·53d. per head of the population. In this sum, however, is included main drainage, the prevention of the pollution of the Thames, and the cost of some of the parks and open spaces. Now these are all matters of vital importance to the public health, but as they are not administered from the medical side I pass them over. For similar reasons I say nothing about the water-supply except to show what powers are possessed in this connexion by the sanitary authorities, though I acknowledge at once that the water-supply of a great city should form a branch of its public health administration.

Certain Government departments exercise authority through medical channels. The Home Office administers the Factory Act for the whole of Great Britain. Its chief inspector is a medical man with a medical staff and locally there are factory surgeons. The Secretary of State for the Home Department deals with schemes for housing the working classes which have been prepared by medical officers of health and officers of the Council. The Local Government Board is the particular department having Poor-law and sanitary administration under its control. Its medical inspectors make reports on epidemics such as that of small-pox at Gloucester and that of typhoid fever at Maidstone, on phosphorus poisoning in match-making, on the lead industries in the north of England, and on sewage-contaminated oysters. The Board of Trade has certain quasi-medical duties with regard to food unfit for consumption.

The London County Council is responsible for several details of health administration. It has its staff of medical officers and sanitary inspectors. It has authority over the vestries and district boards in the metropolis and where any default is shown to exist it can compel these boards to perform their duties. The Council stands on a different footing from other county councils and from large municipalities in that it possesses administrative functions inherent in both counties and cities and also that it has the power of reviewing the action of local authorities within its area. It makes by-laws for the prevention of nuisances and these by-laws the vestries must enforce or the Council may institute proceedings against them. These nuisances relate to bad drains, ashpits, accumulations of refuse, removal of dust, the bad ventilation of workshops or their uncleanly or overcrowded condition, the emission of black smoke from chimneys, and the non-provision of sanitary conveniences in connexion with workshops and dwellings. Nuisances from dust and filth in the streets, from offensive matter emanating from manufactories and from slaughter-houses, the paving of yards and the keeping of animals—indeed, almost everything likely to be dangerous or injurious to health—come under its control. I have said something of the powers of the Council with regard to infectious disease. This body deals with the disinfection of houses and clothes and the destruction of bedding. Premises and apparatus are provided for disinfection and free temporary shelter and in cases of death from epidemic disease the Council provides for speedy interment. The by-laws with respect to disinfection of carriages which have conveyed persons suffering from infectious diseases are particularly strict. The Council deals with offensive businesses. It inspects and makes by-laws for slaughter-houses and knackers' yards. It may cause all dairies and milkshops to be registered and it makes regulations for the inspection of these places as to space, ventilation, lighting, and cleansing, and for precautions against infection. The vestries prohibit the sale of milk where infectious disease exists. Then the vestries have power over the sanitary condition of bake-houses. Their medical officers of health inspect shops and enforce the law with regard to diseased meat and unsound food. The London County Council may require water companies to give a constant supply and it may apply to the Local Government Board to alter the regulations of the companies. The Local Government Board tests the water supplied by the companies as do also the vestries and I need scarcely say that the London County Council promotes Bills in Parliament relating to the water-supply. It has recently spent £40,000 in this manner. Then in the absence of prescribed water-fittings and premises deemed unfit for occupation the vestries can proceed as in the case of a nuisance and may compel the owner to provide a supply of water. If the water is cut off the owner must close the house. Before a new house can be occupied the vestry must certify that it has a sufficient water-supply and it can enforce the cleansing of cisterns. The company, too, must give notice before cutting off the water-supply. The vestry can take proceedings to close houses unfit for human habitation. It can deal generally with overcrowding and it has powers with regard to underground rooms which are unsuitable for dwelling places. I ought to speak of the important work of the Port Sanitary Authority, but time fails me.

With regard to the work of the public analysts employed by the local authorities it is impossible to read the report published by the Local Government Board without seeing how important it is and what protection it affords to the very poor who are compelled to buy their food at the cheapest rate. We read of the substitution of margarine for butter, of cream being taken off the milk and replaced
by water, and often with what the report calls quite medicinal
doses of boric acid. What would be the case if there was no
fear of analysis of these articles and no fine for their adul-
teration? The local authorities might do much more with
regard to houses let in lodgings if they would only put into
force the powers conferred upon them. They make the by-
laws but they do not register the houses, and thus they lose
an easy method of closing a house unfit for habitation. I
am quite aware of the answer made by the local authorities,
that if you drive these people from where they now are
it will be to some place more crowded and less decent.
More accommodation is needed. This is the reply we
got in Bethnal-green. Yet the London County Council
here has built a miniature city of artisan dwellings
on the Boundary-street area and in the most hygienic
and picturesque fashion. The fact is these dwellings,
cheap as they are considering the many advantages they
give, are for the better-class of workmen and they are quite
out of the reach of the poor costermonger whose favourite
quarter is Bethnal-green. I still believe if some Peabody
could arise and clear away the slums and erect buildings suit-
able for the very poor that a small return on the capital could
be obtained. The London County Council is too hampered
in its operations with insanitary property. It has too high a
standard for its buildings. The medical officer of health
having drawn attention to the slum, if the scheme is feasible
and the consent of the Home Secretary has been obtained,
the Council or the local authority, or both, proceed to clear
the site under compulsory powers. Then so many must be
re-housed on the spot, so many within a mile. Few, if any,
of the old residents occupy the new accommodation provided
for them. We ought with cheap trains and tramways
worked by electric traction to get more into the country.
We ought to lessen the obligation to employ the site only
for housing the working classes and thus be able to provide
accommodation a little distant from the spot which has
been cleared. Some of the land could then be sold
for commercial purposes and the clearing of the

London slums could then proceed at a more rapid rate. So valuable is land in the metropolis that no doubt in time by a process of evolution all property of the nature we are discussing will be pulled down to make way for warehouses and offices which pay better, but we cannot wait for this. In the proposed Holborn to the Strand Improvement the cost of land for housing will amount to £260 for each person while within 1½ miles it would be £9. The liability to have to pay the whole cost of the land in sixty years is absurd.

THE ADVANCE OF THE MEDICAL OFFICER OF HEALTH.

From what I have said I think you will see that the medical officer of health is becoming every day more and more highly specialised and more able to cope with the prevention of disease and of insanitary conditions. Elected by the local authorities and partly paid by the London County Council and controlled by the Local Government Board, could the mode of appointment be improved? Do not the trammels of local influence, not to say the routine of their office, dwarf some of their powers for good? Sir Benjamin Hall's Act which created vestries has been in operation only about forty years, but during that time the death-rate in London has fallen one-half. England has always been the pioneer of hygiene, but if she has something to teach she has also something to learn. Ignorance, says a recent writer, pervades the minds of a large section of the public as to the elementary laws of ventilation as shown in the stifling air of churches, theatres, law courts, schools, and even bedrooms; the smoke-polluted atmosphere of our large towns continues with little effort to alter it. We are indifferent to the dangers arising from the consumption of tuberculous meat and milk, yet a Royal Commission has lately reported that any person who takes tuberculous matter into the body as food incurs the risk of acquiring tuberculous disease; and again as long as animals suffer from tuberculosis so long will there exist a fertile source of that disease among human beings. The Commissioners recommend the abolition of private slaughter-houses and the establishment of public abattoirs, and certainly we must have an improved inspection of our meat, whether killed in London or elsewhere. The inspector at Deptford told the Royal Commission that he often examined 1000 *carcasses a day; what could such inspection* be worth? The case of milk is even worse. Meat at least is always eaten cooked and so the dreaded bacillus is generally killed, but milk is often taken raw, though it could be heated and cooled in a way that would impair its taste but little. Some experiments of Professor Delépine show that out of 93 specimens of milk taken at random in Manchester 17 were tuberculous. It does not follow that every child who drank of this milk would get consumption, though the danger to one with a sore mouth would be very great, but there can be little doubt that a large part of the increasing tuberculosis of *childhood is due to tuberculous* milk. The need, therefore, of skilled supervision of the milk supply is very great. Again, tuberculosis does not exhaust the dangers of milk, for typhoid fever and other diseases are unquestionably spread by this means.

And now, though I have not exhausted my subject I have, I fear, exhausted your patience I think I have shown you the need of overhauling our health administration. It wants simplifying. There are too many authorities. It is not a case for more decentralisation but for more centralisation, for a general, uniform, coherent system. The Government, indeed, might well initiate some fresh legislation. We have a Prime Minister's authority for saying, "It is not the rearranging of political machinery; it is the improvement of the daily life of the struggling millions and the diminution of the sorrows which so many are called upon to bear which is the task, the blessed task, that Parliaments are called into existence to perform."

A CASE OF MOVEABLE THIRD KIDNEY.

BY W. WATSON CHEYNE, F.R.C.S. ENG., F.R.S.,
SURGEON TO KING'S COLLEGE HOSPITAL; PROFESSOR OF SURGERY, KING'S COLLEGE.

IN the following case an independent third kidney was found on abdominal section and the extreme rarity of such a condition induces me to place it on record. Here a well-developed kidney was found on the right side of the lower part of the spinal column just at the brim of the pelvis, having its own ureter and blood-supply, and distant about from 3 to 4 in. from the right kidney, which was felt in the right loin and apparently of normal size. The hand passed up into the left loin also grasped the left kidney which was somewhat smaller than the right. In this case the symptoms were no doubt due to the mobility of the kidney and probably to slight pressure on, or kinking of, the ureter.

As regards anatomical literature I have consulted Professor Hughes and find that very little has been said about supernumerary kidneys. In the tenth edition of Quain's Anatomy, having referred to the common malformation—viz., horseshoe kidney—and to the absence of one kidney, the writer says: "The occurrence of an additional kidney is extremely rare; the supernumerary kidney is placed either in front or on one side of the vertebral column or in the pelvic cavity." In most standard works there are only statements to a similar effect. Debierre ("Traité d'Anatomie") relates a case recorded by Gavard where three kidneys were situated against the lumbar spine, the ureter of the central kidney opening into the ureter of the right kidney. This he regards as a case of complete division of the right kidney. There are also cases recorded by Adami, Day, and Halasy of complete double ureter attached to one kidney and several cases of single (lateral) kidney by Birmingham, Dwight, Menzies, Mackey and Koch, and Tweedy. The following are the facts of the case which came under my observation.

A woman, aged twenty-two years, had been under the care of Mr. Coalbank of Teddington for some time suffering from indefinite abdominal pain, indigestion, and a general hysterical condition. The only special feature in the *symptoms* was that when the pain was severe there was diminution in the quantity of urine passed. On examining the abdomen Mr. Coalbank detected a swelling below the umbilicus which was tender and corresponded to the chief seat of the pain. Early in January, 1898, I saw the patient with him and examined her under chloroform. An irregular, flattened, tender swelling was readily felt behind the right rectus muscle at the brim of the pelvis. The swelling was somewhat but by no means freely moveable and had a nodular character. It could not be felt from the pelvis and evidently had no connexion with the pelvic organs. As to *the exact nature of the swelling we could not arrive at a* definite opinion. The idea of a moveable kidney which presented itself among other suggestions was discarded on account of the situation of the tumour and the fact that it could not be pushed into the loin. As, however, it was evidently the chief source of the patient's trouble it seemed desirable to explore and ascertain the exact nature of the swelling and see whether anything remediable could be done. This I did on Jan. 18th, 1898. On opening the abdomen in the middle line it was found that the tumour was situated behind the peritoneum resting on the *right side of the lower* lumbar vertebræ and the brim of the pelvis. The peritoneum having been divided over the swelling and some fat around it having been cleared away it was exposed and presented the appearance of normal kidney substance. It was now thoroughly protruded through the opening in the peritoneum and presented the shape and size of a normal kidney except that it was distinctly lobulated. The hand was then passed up into each loin and a kidney found normally situated on each side, as has been already stated (this fact was verified a second time before the abdomen was closed). The *condition* was thus clearly one of supernumerary kidney and the patient's trouble was essentially due to slight mobility of this organ. I made no attempt to fix the kidney by stitches as that would have been very difficult and I hoped that the tearing and disturbance necessary to expose it would lead to such adhesions as would sufficiently fix it in its place. The kidney was therefore returned to its former position, the peritoneum was brought together over it, and the abdominal wall was closed in the usual manner with deep and superficial stitches. On Jan. 4th, 1899, Mr. Coalbank writes to me that the *patient* "has lost her usual plaintive frame of mind and is well and happy; she has had no medical attendance since her return from the seaside after the operation."

Harley street, W.

BUDLEIGH SALTERTON COTTAGE HOSPITAL.—The annual meeting of this institution was held on Jan. 12th. The financial statement showed [illegible] in hand of £72.—On the motion of Dr. R. W. [illegible] decided to [illegible] patients at a [illegible] weekly.

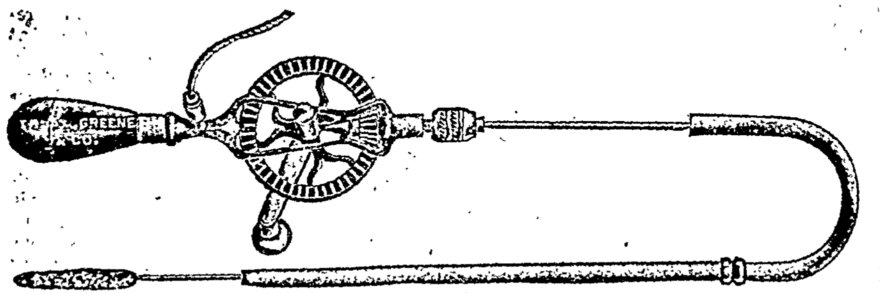
NOTES ON THE DEMONSTRATIONS OF METHODS IN GASTRIC THERAPEUTICS.[1]

BY FENTON B. TURCK, M.D.,
PROFESSOR OF GASTRO-ENTEROLOGY IN THE POST-GRADUATE MEDICAL SCHOOL, CHICAGO; MEMBER OF THE AMERICAN GASTRO-ENTEROLOGICAL ASSOCIATION, ETC.

THE first essential element of rational therapeutics is a correct diagnosis based on the history of the case, its symptoms as observed by the physician, and thorough and exact methods of clinical examination. The evidence of the anamnesis and rational symptoms is as important in its way as any part of the general examination by means of such instruments of precision as the microscope, the test-tube, and all other paraphernalia of the medical laboratory and ought not to be undervalued. After all the data from all these sources are obtained he is best able to correctly diagnose the case whose judgment, ripened by study and experience, can best select and compare all the facts, giving each one its proper value, and then can estimate and harmonise the whole. The chemical methods of examination in gastric diseases have been carried by the Germans to an extreme refinement. Since Ewald first introduced the soft rubber stomach-tube this has been most extensively utilised in variously modified forms for both diagnostic and therapeutic purposes. The German literature on the chemical examination of the gastric contents by the use of the tube would fill many volumes and yet after twenty years' experience we find that little dependence can be placed upon the chemical methods and their results for diagnostic and therapeutic purposes as compared with those of directly mechanical methods. In 1894 I had the honour to present before the International Medical Congress in Rome a method for examining the stomach that looked more into the physical condition of the organ than into the chemistry of its contents. Demonstrations of the method were also made in that same year at Vienna, Berlin, and other cities.[2] Without going into any criticisms of the various other instruments and methods devised for the purpose of determining the position and physical condition of the stomach, some of which methods have done, and undoubtedly still do, great service in the hands of sufficiently skilled and experienced physicians, the medical profession is, I think, still in want of a rapid and practical method by means of which the position, size, and motor power of the stomach can be determined with accuracy and in all varieties of morbid states.

One of the instruments and methods there described for the first time in Europe, somewhat modified and considerably improved during the four intervening years of clinical practice and experimentation, I now present to you (Fig. 1).

FIG. 1.



The gyromele or revolving sound, with sponge attached to the cable.

The instrument I have called the "gyromele," though for most of you the term "revolving sound" may be more familiar and descriptive. It consists of a flexible rubber-coated steel cable, to one end of which is attached a soft sponge and to the other an apparatus for producing revolutions, not unlike a surgical drill. When the instrument is to be used the cable is first slipped through a rubber tube long enough to reach through the œsophagus to the cardiac opening and cable and tube are then introduced into the stomach. The cable and sponge are then pushed further down into the stomach and the drill is attached to the external end. As the now rotating and vibrating cable is pushed further down the sponge glides along the greater curvature, the pylorus, and the lesser curvature; while the cable adjusts itself to the shape of the stomach, and its motions can be distinctly felt by the hand upon the abdominal wall.

From the evidence of several hundred cases upon which the gyromele has been used both for diagnostic and therapeutic purposes during the last four years I believe that we can safely conclude that by means of this instrument it is possible to determine with practically absolute certainty—1. The exact outline of the stomach on the abdominal walls, the greater curvature, the lesser curvature, the fundus, and the pylorus. 2. The character of the stomach walls: (*a*) any considerable thickening of the walls is unfailingly discovered because of the varying ease and plainness with which the sponge revolved against the wall can be felt on the outside; and (*b*) the distensibility of the stomach can be more readily and more accurately determined by simply using cables of different degrees of flexibility than it can be determined by any other method. From its distensibility the motor power can be quite accurately estimated in cases where there is no pyloric obstruction, as has been repeatedly found by experiment. The pyloric obstruction if present is discovered in the process of the sounding of the stomach, pylorus, and duodenum. 3. In addition to the above complete diagnosis of the physical condition of the stomach the gyromele has been found to be an unfailing means of discovering atrophy and, indeed, of distinguishing atrophy from functional achylia. This is due to the fact that the revolving sponge is quite as effective as any test meal for stimulating the secreting glands to almost immediate activity. On withdrawing the cable the sponge is found saturated with the gastric contents and this furnishes ample material for bacteriological and qualitative chemical tests. If the gyromele is allowed to remain in the stomach for a few minutes (which does not inconvenience the patient) the stomach contents will within fifteen minutes invariably contain HCl unless there be atrophy of the HCl secreting cells. In order to thus determine with certainty the presence or absence of cellular atrophy the gyromele is revolved a little longer than usual and the stomach contents are examined about fifteen minutes after the withdrawal of the gyromele cable. The contents will then invariably contain hydrochloric acid unless there be glandular atrophy.

Before proceeding to practically demonstrate the use of the gyromele for these purposes it may be as well to call attention to the objection which has been raised against it by some on the ground of danger to the patient. This objection is wholly unwarranted so long as there is no case on record where the gyromele has produced injury to a patient. Neither in private practice nor in the large hospital practice of myself and my students has there ever occurred such a case and I have yet to hear of it from any other source. The gyromele is, in fact, less dangerous than the universally used stomach tube for the simple reason that the end of the cable is of sponge and this when wet, and especially when covered with mucus, is as soft and slippery as the mucous membrane itself. The reason for ascribing such danger to the use of the revolving sound must be the fact that it can be so easily and distinctly felt through the abdominal walls, but this is due simply to its rapid motions and vibrations which are very perfectly transmitted through the abdominal tissues and the patients soon become so accustomed to the gyromele treatment that its use does not produce any marked feelings of distress. In addition to the above I must also, in justice to myself, defend my priority in the introduction of the flexible sound as against the claims of Dr. Kuhn of Giessen. The flexible revolving sound was used and described for the first time in Europe by me in 1894 as has already been stated. Its utility for sounding all regions of the stomach and duodenum as well was clearly set forth in my demonstration at Rome in that year, while Dr. Kuhn's first publication on this subject appeared in 1896. Since Dr. Kuhn in his publication makes no mention of my much earlier work on the subject it must be supposed that he knew nothing of it at the time. Be this as it may, the fact remains that he has not added a single new feature to the instrument which was shown in 1894 and his claims to priority either of the instrument or of any method of using the same is, to say the least, in every essential unwarranted.[3] We will now proceed with the demonstration.

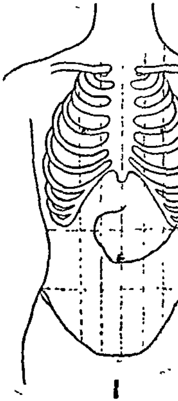
---

[1] Abstract of Demonstrations and Lectures given at St. George's Hospital, London, on August 8th, 9th, and 10th, 1898.

[2] Wiener Klinische Wochenschrift, 1895, Nos. 1 and 2.

CASE 1. (August 8th, 1898).—The patient, a woman, aged fifty-one years, began to have stomach trouble about a year ago and since that time has continually grown worse until she at present is so weak that she cannot leave her bed. The food that she eats, as well as the gastric secretions, seem to accumulate in the stomach until she is forced to vomit so as to obtain some relief from her distress. The vomited matter shows all the characteristic indications of retention. Examination shows general emaciation with panniculus adiposus absent. There is no cachexia. The chest organs are almost negative as regards physical signs. The abdomen is retracted in the left epigastrium and in the umbilical regions a bulging may be observed. This is due to the enlarged stomach as is shown by slight peristaltic movements, which can be recognised. Yesterday, three hours after a meal consisting of beef and bread, we found on passing the "intragastric reagent capsule"[4] into the stomach that the Congo paper and the dimethyl amidoazo benzol paper showed no free HCl, while the litmus paper indicated a faintly acid reaction. To-day on withdrawal of the stomach contents ten hours after a meal we find again no free acid and we do find quantities of food particles. We now introduce a very flexible gyromele with the patient lying on the bed, and by the palpating the revolving sound upon the abdominal wall we locate first the greater curvature at the umbilical line, and by pushing the cable further into the stomach until the revolving sponge impinges against the lesser curvature we find it located just below the border of the left lobe of the liver. On withdrawing the gyromele and testing the liquid which can be obtained by squeezing the sponge we find again that there is no HCl present in the stomach. The outline and position of the stomach as thus determined are shown by the diagram (Fig. 2).

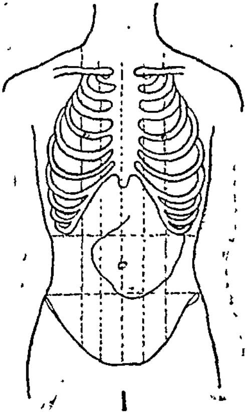
FIG 2



The outline of stomach as given by the movements of the light flexible cable.

In order to determine the degree of distensibility of the stomach we now pass in a gyromele having a somewhat less flexible cable than the one just used and again determine the outline of the stomach by palpating the revolving and vibrating sound. This time with the patient sitting upright we find the greater curvature below the umbilical line and quite near the hypogastric line while the lesser curvature can be distinctly outlined just above the epigastric line. As shown with this second cable (see Fig. 3) we find that the stomach is only slightly dilated but that this is a case of marked gastroptosis with very lax ligaments, the stomach being freely moveable in its position. The long duodenal cable is next introduced for the purpose of sounding the pylorus. The sound is obstructed as it reaches the pylorus and further pushing only elicits signs of pain. The tip of the revolving sound can easily be recognised and the palpation indicates a hardened and thickened pylorus, but no tumour can be felt.

FIG. 3.



The outline given by the movements of the less flexible cable.

From the tests thus made we arrive at the following diagnosis:—1. Absence of free HCl after various test meals together with the failure of the gyromele to produce a secretion of the acid would indicate atrophy of glands. 2. The slight dilatation of the stomach, together with the ease with which the whole viscus can be pushed downwards, as shown by the use of cables of different flexibility, indicates the presence of gastroptosis and the thickened walls show hypertrophy. 3. The long retention of the food indicates either motor insufficiency due to myasthenia or pyloric obstruction and as the duodenal sound indicates a hardened and thickened pylorus we conclude that this is a case of stenosis pylorica. In view of the fact that the pyloric obstruction, notwithstanding the marked hypertrophy, is almost complete I recommend immediate operation.

[Through the courtesy of Dr. Ewart, the attending physician in charge of the case, the following hospital report has been received:]

"Operation was performed by Mr. Jaffrey on August 17th. No outlying mass of cancer or glands could be felt. The stomach was of moderate size with thick muscular walls and did not reach below the umbilical level. Owing to its dropped state it could be easily pulled through the incision as well as the pylorus. The pylorus and its vicinity were free from peritoneal adhesions or thickenings. There were a few superficial pyloric venules and minute whitish specks but no important engorgement. The gall-bladder was greatly distended with bile. Marked thickening could be felt not only at the pylorus but 1 in. or 2 in. along the duodenum and 2 in. or 3 in. along the lesser curvature. This decided Mr. Jaffrey to prefer gastro-jejunostomy to pyloroplasty and this was accordingly performed with satisfactory results, the patient doing well for two days. On the third day she began to vomit. Exhaustion set in on the fourth day when she died. At the necropsy no tympanitis or peritonitis could be found. The external and the stomach wounds were sound. The thickening which had [illegible] was found to be almost entirely muscular, traversed from within by a few fibres from a thin radiating deposit with white fibrous tissue in the submucous layer. In connexion with this the mucous membrane at the pylorus and for 1 in. beyond was atrophied, glistening, and striated.

---

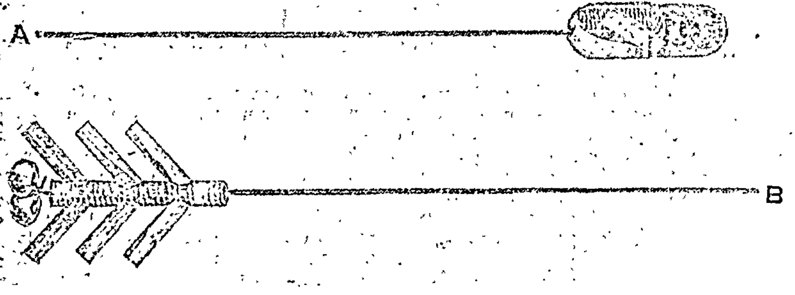
[3] Turck: Die Priorität der Sondirung von Œsophagus, Magen und Eingeweide mittels der Gyromele (biegsamen Revolvirsonde), Centralblatt für Innere Medicin, No. 8, 1898.

[4] See Fig 4.

"There appeared to be nothing in the case, judging from these appearances, incompatible with complete recovery from the gastric dilatation, as well as the gastroptosis, had the patient's strength been equal to the surgical ordeal. The case tends to show how slight may be the impediment which leads to these fatal results."

From what has just been said in regard to the use of the gyromele it must not be inferred that this instrument is the one thing or the only one to be used in the diagnosis of diseases of the stomach. On the contrary I would insist that the successful diagnostician of these diseases must have at his command all the methods which have been shown to be valuable, and to such an extent that he will know how to vary them in their application to the needs of each particular case. The test meals and the soft rubber stomach tube, for example, are devices for which the profession must gratefully remember their originators. Moreover, cases arise where the stomach tube as well as the gyromele fail us for the simple reason that we dare not use them. Various more or less successful devices have been got up to meet the needs of such cases.[5] In how far these meet the requirements of European practitioners I do not know, but I have found the following method to be of great value where the stomach tube cannot be used. In the *Journal of the American Medical Association* for April 23rd, 1898, I presented a device called "intragastric reagent capsule" which does possess decided advantages over the older sponge tester, silver bucket, pith-pellets, &c. The intragastric reagent capsule contains a small piece of rubber drainage tube about an inch in length slit so as to carry three test-papers. Through the tube is passed a silk thread carrying a good-sized lead shot at the end. The tube with test-papers and the shot are enclosed in an ordinary gelatin capsule. The capsule is easily swallowed and sinks readily to the bottom of the stomach. In five minutes the capsule will be dissolved, the test-papers will be saturated, and the tube will be filled with the stomach liquid that will not run out because the lower end will be closed by the shot. When the string is withdrawn the three test-papers coloured with litmus, Congo red, and dimethyl-amidoazo-benzol paper respectively will at once indicate the chemical nature of the stomach contents. The liquid in the tube can be used for duplicating the tests or for microscopic examination.

FIG. 4.



A, the intragastric reagent capsule, containing the indiarubber tube, reagent papers, and lead shot, as shown in B.

CASE 2.—This patient, a robust-looking young woman, aged twenty-two years, has just entered the hospital with the diagnosis of ulcer of the stomach. She complains of a penetrating pain in the left epigastrium, near the costal arch. She has had frequent spells of vomiting, these sometimes passing into paroxysms of pain, when the vomited material would contain more or less blood. The physicians in charge have on the strength of these symptoms, upon which Brinton has laid especial stress, made a diagnosis of ulcer and have referred the case to this hospital for treatment. It is easier to describe characteristic symptoms of ulcer of the stomach than to make the diagnosis at the bedside. In at least 75 per cent. of the cases of ulcer there is an increase of the HCl and the other 25 per cent. show hypochlorhydria or very rarely a case of achylia. Therefore, if the excess of HCl is found together with the above three characteristic symptoms, localised pain, vomiting, and hæmorrhage, the diagnosis of ulcer would be very much strengthened. But we are prevented from determining the state of the gastric secretion by the danger of passing the stomach tube and by opposition from the patient. We may, however, have the patient swallow this intragastric reagent capsule which is neither more dangerous nor more difficult to swallow than a bolus of food. The capsule is weighted inside by means of a good-sized shot and its rapid entrance into the stomach is hereby ensured. We wait five minutes, allow the capsule to dissolve so that the test-papers may come in thorough contact with the gastric contents. On withdrawing the capsule test-papers we find that they are unchanged and that there is therefore no hydrochloric acid present in the stomach; the litmus paper shows there is in fact no acid reaction whatever. Closer investigation now reveals the fact that while the pain is more intense in the region of the costal arch it is also quite diffused over the epigastric region. We also learn that the pain is not particularly increased by taking food and that the hæmorrhage was at no time very profuse. These facts tend to throw considerable doubt on the diagnosis of ulcer. Now since by the use of the capsule the patient's opposition has been lessened we may now pass the stomach tube and on withdrawal of the contents we find that there is no acid present. Having thus found the presence of ulcer highly improbable we must look for other causes of the slight hæmorrhage which has occurred, and as râles can be heard in the apices of the lungs, especially in the right apex, we must consider the possibility of pulmonary hæmorrhage and if this be excluded we may diagnose the hæmorrhage as pharyngeal or œsophageal. Under these circumstances we certainly have no reason to consider this a case of ulcer and may recommend a more vigorous line of treatment.

The following report has since been received (September, 1898): "I may add to the report concerning the young woman that she continued to improve, gained weight as well as strength, and lost the slight râles that we had discovered at the right apex.—Wm. Ewart."

Therapeutics.—The first essential element of rational therapeutics, as was mentioned at the beginning, is a correct diagnosis and these demonstrations illustrate in a measure what was said in regard to having a sure command of the chemical and still more of the physical factors that must be considered in the accurate diagnosis of gastro-intestinal disorders. What is true of diagnosis is emphatically true in therapeutics of stomach diseases. Chemical reagents, medicines, have their proper uses and no conservative physician would attempt to do without them. Medical men are, however, at present agreed that the physical condition of the stomach is of far greater importance than its secretory function and the pathological disturbances are largely mechanical, such as motor insufficiency. The logical outcome of this fact are the modern attempts to improve this physical condition by physical means, such as lavage, massage, exercise, "electrisation," and a variety of mechanical stimulating devices. The gyromele described above is most useful as an instrument of diagnosis. In addition, however, it has a therapeutic value which can scarcely be over-estimated. It removes mucus and other adherent débris from the entire inner gastric surface and by subsequent use of the needle douche[6] the stomach can be cleansed far more perfectly than by any other method. By means of the gyromele any desired antiseptic can be applied to the entire surface of the stomach; the combined rotatory-vibratory motions of the gyromele give at the same time a very stimulating massage to every part of the organ. That the massage given by means of the gyromele must be very effective is evident when we consider that the mere contact with solid food in the stomach is sufficient to stimulate the circulation in the gastric walls and to produce the muscular contractions by which the food is churned during digestion. A systematic massage by means of the gyromele improves rapidly the motor power and the circulation of the stomach and these results are in turn followed by a diminution of the mucus and often by a restoration of the secretory function to normal conditions In addition to these patent advantages of this instrument it has been found to act better than any other electrode for electrical stimulation because it permits direct application at any desired area of the stomach walls For these reasons the gyromele is used in my private and hospital practice and clinics more extensively than any one other device

[5] Edinger: Deutsches Archiv für Klinische Medicin, Band xxix., p. 555. Einhorn: Medical Record, July 19th, 1890. Spaeth: Münchener Medicinische Wochenschrift, Band xxxiv., 1897, p. 1011.

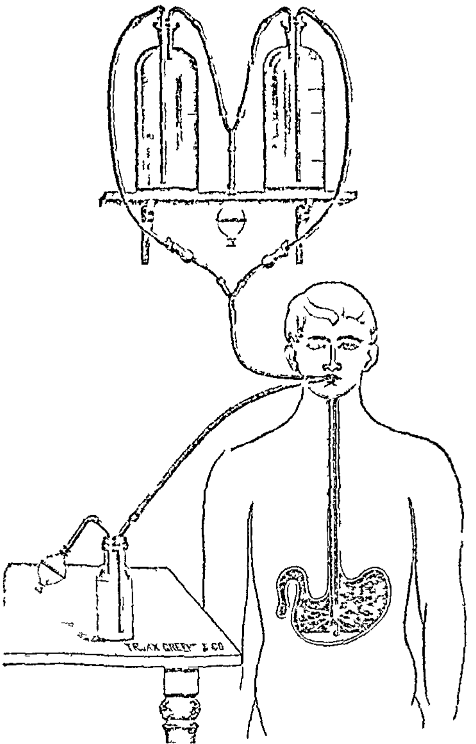
[6] Journal of the American Medical Association, June 22nd, 1895.

The intragastric resuscitator which I show here needs but little description (Figs 5 and 6) It consists simply of a double stomach tube[7] to one end of which is attached a soft rubber bag[8] which was originally devised for the purpose of reducing surgical shock and collapse[9] The bag when collapsed fits closely around the stomach tube and is easily introduced into the stomach Its use and purpose in gastric therapeutics can be illustrated upon the following case

CASE 3 —This patient, a keeper of a public house forty two years of age is suffering with Raynaud s disease The patient is unable to walk and for the last six weeks has been confined to his bed The hands are pale (local syncope) and the feet are bluish (local asphyxia) There is a complete absence of radial pulse and the heart beat is small and feeble The abdominal physical symptoms are negative The temperature in the axilla is 98 8° F in the rectum it is 99 2°, and on the skin (inner side of the calf) 92 1° The patient was given a bath about an hour ago, we now introduce the intragastric resuscitator The double tube with attached rubber bag is passed into the stomach and we pass a continuous current of water through the tube and bag beginning with water of 125° F and gradually increasing its temperature to 130° In surgical shock we use temperature as high as 135° The water is cooled in the stomach by the rapid transmission of heat to the tissues but as the current of water is continuous the high temperature is maintained and this acts as a powerful vaso motor stimulant upon the œsophagus the stomach walls and upon the splanchnic area and also reflexly on the heart As the œsophagus and gastric walls become heated as well as the great vessels in proximity the warmed blood is rapidly carried to the periphery by the circulation stimulating the cells and producing a dilatation of the previously contracted peripheral arterioles The congestion of the splanchnic area is also rapidly reduced and a more abundant supply of blood is carried through the heart The heart beats in consequence become stronger, the hands and feet begin to show warmth, and the improved colour of the skin can be observed as the treatment is kept up This is particularly noticeable under the finger nails where the normal pink shade is gradually replacing the pale whiteness observed before we began the treatment Half an hour's treatment is sufficient We syphon off all the water from the bag and remove it and the tube from the stomach The extremities now show warmth the colour of the hands and feet is much improved the eyes are bright and the face presents quite a rosy tint The patient feels stronger, is able to get out of the bed and walks supporting himself to a rolling chair, and seems in general to be very much strengthened The heart area is normal, the beat is full and strong and there is no reduplication of the heart sounds The temperature one hour after treatment per rectum is 100°, in the axilla it is 96 6° and on the skin it is 95 5° (According to a later report the patient left the hospital much better and stronger This case was used for the purpose of demonstrating the method of using the intragastric resuscitator and to show its physiological effects)

The advantages of the intragastric resuscitator are —1 The heat is applied in a uniform and diffuse manner of much higher temperature than dare be used with water in direct contact with the mucous membrane The temperature here used (from 130° to 135°) is in most cases necessary in order to produce the desired stimulation. 2 The exhaustion produced by passing large quantities of warm water directly into the stomach (which dilates the splanchnic vessels) is avoided while the hot water used by the above method produces stimulation of this area without exhaustion 3 The removal of the necessary secretions and nutrient material is entirely avoided 4 The degree of temperature as well as the quantity of water used within the bag is under the complete control of the operator

FIG 5



The intragastric resuscitator apparatus for the needle douche and for washing out the stomach

Fleiner refers to lavage as follows ' The changing distension and emptying of the stomach act upon the walls of the stomach like local gymnastics Motility is rapidly improved atony disappears ' &c (Quoted from Baruch's Principles and Practice of *Hydrotherapy* 1898 p 280.)

A more effective and satisfactory method for giving the stomach this exercise has been used for some years in my clinics and private practice The alternating distension and contraction of the stomach is more perfectly accomplished by the use of air instead of water

Pneumatic gymnastics of the stomach —By this means the distension is more uniform in all directions and the objections to the heavy load in an already prolapsed, dilated and weakened stomach is entirely avoided Moreover, the dilatation by the use of water takes place in one direction only—namely, downwards—while the air acts equally on all sides giving all the musculature of the stomach that most effective extension and contraction which is known to be so valuable to weakened muscles of other parts of the body. I had the honour to present at the recent meeting in Edinburgh by invitation of the British Medical Association a full description with reports of experiments and cases of the apparatus and methods used to produce pneumatic gymnastics.[10] The method briefly is as follows. A double stomach tube is introduced into the stomach and is connected on one side with a manometer and on the other with a compressed air cylinder. The cyclinder has previously been filled with air at rather high pressure (3 or 4 atmospheres) by means of a small hand-pump. By then opening a stopcock of the cylinder air is allowed to distend the stomach until the manometer connected with the closed exit tube indicates the desired pressure. The stopcock is here closed and the exit tube is opened. The compressed air in the now quite distended cavity rushes out and the gastric muscles contract vigorously, aided by the contractions of the abdominal muscles.[11]

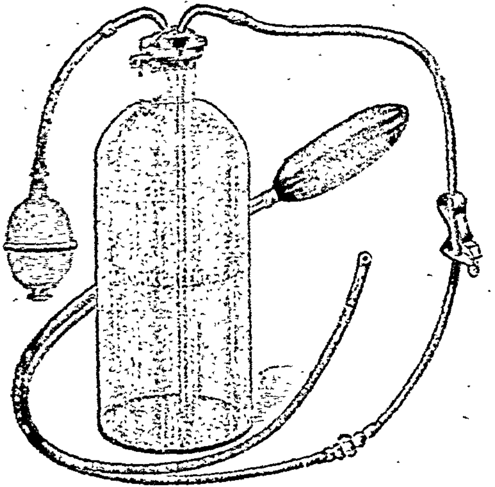
[8] Journal of American Medical Association, June 11th 1896

[9] Turck Surgical Shock ibid June 19th 1897

This exercise can be repeated from twenty to thirty times in the course of a few minutes and a regular course of this exercise will frequently produce a very rapid improvement in the motor power of the organ even after other methods of treatment have failed. Another most remarkable effect of this treatment is the improvement of the local and general circulation noticed very early even by the patients. The experiments upon animals just referred to demonstrate a marked effect upon the splanchnic and ultimately upon the peripheral circulation. By passing the air through heated water (from 50° to 65° C.) we can introduce heated vapour at a controlled temperature into the stomach. The effect is most remarkable and the method has none of the disadvantages of lavage.

FIG. 6.



The intragastric resuscitator: the gastric end of the double tube covered by the dilateable soft rubber bag.

In the above are briefly indicated the most important original methods of diagnosis and therapeutics which are constantly used in our clinics and practice. More detailed descriptions of these have already been published in American periodicals,[12] but constant use naturally gives rise to modifications and improvements of instruments and methods. Some such, at present on trial, it is hoped can be reported upon in the near future, also some other points not touched upon here.

THE PRESENT POSITION OF THE QUESTION OF OPERATION IN UTERINE FIBROIDS.[1]

BY E. STANMORE BISHOP, F.R.C.S. ENG.,
SURGEON TO THE ANCOATS HOSPITAL, MANCHESTER.

ALTHOUGH the consideration of this subject appears at first sight more fitted for a society of gynæcologists than for a clinical society it is well sometimes to report progress in any special work to those whose professional duties necessitate a more general range of information. During the last few years the surgical treatment of fibroid disease of the uterus has undergone considerable change and necessarily consequent upon this the general question as to what advice shall be given to a patient suffering from this disease has assumed new aspects. Speaking generally I believe it may be said that the usual feeling of both patients and the bulk of the medical profession is against active interference in these cases and that this feeling is based upon four reasons: (1) fibroids are not fatal if left alone; (2) fibroids can be made to shrink by the use of ergot and similar drugs; (3) fibroids naturally tend to disappear at the menopause; and (4) surgical interference if it is to be effective imports extreme risk to life. The relative value of the first three depends very greatly upon the amount of force which attaches to the fourth. If this is less true than it undoubtedly was they lose much of their importance, whilst a new set of reasons for operation which previously could scarcely be maintained now become evident and gain in weight in proportion to the amount of change which can be shown.

Before the introduction of asepsis into surgery the mortality of any operation for the removal of fibroid can hardly be said to have existed, since no such operation could safely be undertaken. The course of events has been greatly like that of ovariotomy. Since any new operation must necessarily be somewhat of an experiment it was only in extremely bad cases at first that anything was tried. This meant, of course, that the tumours present were exceptionally large and the prospect of removing them was correspondingly gloomy. Subperitoneal fibroids with a pedicle were removed if single. Submucous fibroids, also pedunculated and those which had become polypoid were taken away, but interstitial fibroids, especially if multiple, were carefully left alone. If the tumour projected sufficiently towards the uterine canal, this was dilated, the capsule divided, and the tumour either enucleated at once or allowed to gradually extrude itself. If the first was possible recovery often followed, but if the latter the risks of gangrene of the tumour were very great. Tait had 8 cases of this kind with 4 deaths. The operation then most in favour—due, no doubt, to his powerful advocacy—was removal of the ovaries and tubes. In his latest book he gives a list of 262 cases with 4 deaths, exclusive of his earlier cases which had a mortality of nearly 25 per cent. The latter list, it will be seen, has a mortality of only 1·53 per cent. The mortality in Thornton's hands was just over 4 per cent. Such a mortality is certainly low enough to demonstrate the safety of the operation, but the mere mortality is not of course the only point to be considered even if in other hands it could have been maintained. Of far more importance is the effectiveness of the operation and its ultimate result. The result of this method as a rule was a decrease in the size of the tumour and cessation of flooding, but this did not follow in all cases. In some the tumour not only did not decrease, but it went on enlarging, and especially was this the case in fibro-cystic tumours. These apparently were not amenable to this operation at all. Unfortunately these were precisely the tumours which gave most trouble, caused the greatest loss of blood, and as to which even the normal menopause could not be relied upon to give relief. Moreover, in many of the worst cases, those in which surgery was most imperatively needed, it was noticed that whilst it might be possible to remove one ovary and tube it was well nigh impossible to reach the second whilst the tumour remained, and the essential of success being the total removal of all ovarian[2] and even tubal tissue up to the uterine cornu (Tait), the operator might find that after all his work was useless. Now, as such patients were worn down by loss of blood and pain beforehand, after such an operation they were but so much the worse. Johnson believes that the average failures amount to about 10 per cent. The opinion, meanwhile, was gaining ground that the ovaries like the ductless glands were essential to the general equilibrium, so that this operation was open to the double objection that whilst it could not be relied upon absolutely to get rid of the tumour and its results—loss of blood and pressure effects—it removed organs which might be perfectly healthy and which were necessary to the good and satisfactory after-condition of the patient. Naturally attention was again directed to the uterus itself. Myomectomy or removal of fibroids *per se* if single was carried out. Great difficulty was, however, sometimes found in closing the resulting cavity safely. Uterine tissue is extremely difficult to suture satisfactorily. It is not always the same, it contracts and dilates. A suture which is firm at the moment of insertion may be anything but firm after the abdominal wall has been closed. Besides, this could hardly be done when, as is so often the case, the fibroids were multiple. Just lately a proposal has been made by Alexander[3] of Liverpool to remove multiple fibroids through a single opening in the uterine wall, but it has not met with much favour. He brought forward 11 cases, and claimed that the uterine walls could be ransacked quite easily through the one incision. Although there was only one death the condition of the uterus itself after clearance in this way does not seem ideal. Moreover one could not be sure that such growths might not start afresh in a uterus predisposed to fibroid degeneration. This operation, however, may be said to be so lately brought forward that sufficient time has not elapsed for a fair judgment to be formed. Engström[4] in 1896 advocated a similar procedure. He used it in 100 cases with 5 deaths. In 37 cases there were multiple tumours (from 2 to 5) and once there were 22 tumours. In 3 cases there was return or fresh growths developed. There were 3 returned in 113 cases reported by Martin.

[1] A paper read before the Clinical Society of Manchester on Jan. 17th, 1899.

But attempts were now made to remove the uterus itself with its contained growths, leaving the ovaries and tubes behind, if healthy. The methods adopted followed almost precisely the same route as previously ovariotomy had taken. The uterus was delivered through the abdominal opening; its base was encircled by a wire serrenœud, and the main bulk cut away—the period of the clamp. Of course the pedicle became adherent to the abdominal wall. There was the same, only more prolonged and dangerous, period of separation of the stump, the same dragging afterwards upon the pelvic and abdominal tissues and, in addition, the very great risk of inclusion of some portion of the bladder so intimately adherent to the uterus, or the ureters, in the serrenœud. Secondary hæmorrhage also was not unknown and in cases where the fibroid had developed into and between the layers of the broad ligament, the removal of the parts above the bladder was practically useless, since the really effective producer of pain and pressure was left behind. Then the bladder was stripped down and the broad ligaments were opened leaving only the uterine cervix to act as a stump. Hegar's name is associated with this method. Knowsley Thornton may be taken as the great advocate of this extra-peritoneal fixation of the stump. But as operators realised more and more the safety of intra-peritoneal work it was inevitable that attempts would be made to dispose of this stump, as the stump of an ovarian tumour had been previously, so as to be entirely free within the cavity of the abdomen. There was, however, one obstacle to this and it appeared almost insurmountable. The cervical canal must be divided and in it there might be septic bacteria. The pioneers of this operation covered it over with peritoneum, removing a wedge-shaped portion so as to permit the formation of an anterior and posterior lip which were sewn together; in this way the peritoneal sac was closed and it was hoped that sufficient drainage would take place through the cervix into the vagina; Schroeder was the originator of this method. Several surgeons who practised this method had, however, every now and then to dilate up the cervix and let out pus which had accumulated beneath the peritoneum. Byford[5] after removal of the supra-cervical portion of the uterus made an opening in Douglas's pouch and forcibly dragged the upper extremity of the stump through into the vagina, leaving a curved stump of which both orifices pointed downwards.

The mucous lining of the cervix was also destroyed in various ways—by strong carbolic acid, by the actual cautery, or by the electric cautery—but it must be said that none of these methods were entirely satisfactory. The present methods aim at the entire removal of the uterus, cervix and all, and appears to give by far the best results. They are two—panhysterectomy by the abdominal route and vaginal hysterectomy; a combination of both is often found useful. Although these operations are comparatively new already some statistics are available and they are decidedly encouraging. Thus Kelly[6] reports a series of 100 cases, with a mortality of 2 per cent.; Bantock[7] 7 cases, with 1 death, due not to the operation but to chronic ulceration of the colon. Donald[8] in 1886 had 4 cases, with 1 death. Christopher Martin at the same date had 10 cases, with no deaths. Doyen[9] had 35 cases with 1 death; during 1897[10] Martin had 12 cases, with 3 deaths, by abdominal panhysterectomy.

In the execution of both these operations there are several variations in the manner in which they are carried out, the complete description of which would unduly prolong this paper. Péan, Doyen, Segond, and Landau have each introduced some alterations in vaginal hysterectomy, and Martin, Zweifel, Baer, Sänger, Le Bec, and Martin in abdominal, but the ultimate intention in all is to remove entirely the affected uterus, leaving tubes and ovaries unless they are irremediably diseased. The advantages of such an operation are many. By the total removal of the fibroid uterus you get rid once and for all of the exhausting hæmorrhage, the sense of weight and discomfort, the pressure upon the bladder and rectum, the pressure upon the sacral and lumbar nerves, the obstruction to free circulation in the lower extremities; you leave behind nothing which can either start fresh growth or act as a nidus for suppuration, and you do leave behind the all-important ovarian tissue. The cardinal objection is, of course, that you take away also the possibility of pregnancy. Of course this objection applies to all methods by means of which the supra-vaginal portion of the uterus is removed. It remains to be seen whether this objection is worth as much as *a priori* it appears to be. Süsserott[11] says that out of 147 cases of pregnancy complicated with fibroids the forceps were applied in 20, out of which number 8 mothers and 13 children died. In 21 cases in which the placenta required removal by hand 13 women died. Collectively the mortality of the mothers was 53 per cent.; of the children 66 per cent. Tarnier out of 6 cases delivered by forceps lost 4 mothers and 4 children. In 6 cases with version 3 mothers and 3 children died. Five pregnant women with fibroids died before delivery. Sänger collected 43 cases where Cæsarean section became necessary. Out of these 36 mothers died—i.e., a mortality of 83·7 per cent. Pozzi collected 28 cases of Cæsarean section for fibroids; of these 24 mothers died, or over 86 per cent. Johnston says that during pregnancy or labour one-third of the mothers and more than one-half of the children die, so that where the tumour cannot be removed celibacy, he says, is to be recommended. Pregnancy, therefore, instead of being a condition for the sake of which a patient is to be advised to suffer anything, is really one of the complications most to be dreaded; and some writers, as Baldy, even advise operation more in young persons than in those whose chance of child-bearing is reaching its limit.

It is easy to understand why great danger arises in pregnancy. Abortion is frequent in these cases and the fibroid uterus less easily and perfectly contracts. Thus there is great danger of retention of clot or portions of decidua with the consequent septic poisoning. Lefour collected 39 cases of abortion due to fibroids, with 14 deaths. Should the pregnancy reach the normal limit the dangers of parturition are great. If the tumour has developed in the broad ligament it lies an insurmountable obstacle in the route through which the child should pass. Cæsarean section may be required. Sometimes the tumour can be passed by the aid of forceps. In such cases the tumour is apt to be so much bruised that there is great risk of its becoming gangrenous. In some cases the placenta is inserted at the region of the fibroid and furious hæmorrhage will occur during and after its separation, since the indispensable contraction cannot be brought about. If the rate of mortality in these cases be compared with that after pan-hysterectomy a fair idea of the relative risks of operation and no operation will be obtained.

But the mortality having been shown to be small the relative importance of the reasons for hysterectomy becomes much greater. I purposely omit the consideration of electricity in these cases. It only confuses the question, since, although personally I have had one or two fairly good results, the method has been practically abandoned. In 1892 Thornton[12] declared that any man who advised operation in cases which required vaginal examination for its discovery was either a very ignorant or a very wicked person. Kessler[13] in 1896 said it was questionable whether it is not advisable to operate in every instance. He pointed out that in many cases the tumour first begins to grow after the menopause; that persistent hæmorrhage results in fatty degeneration of the heart muscle—the fibroid tumour heart; that gangrene or sloughing of the tumour may occur; now and then they become telangiectatic and cystic, more rarely torsion occurs; then that a fibroid easily degenerates into a sarcoma; and finally, that local compression of neighbouring organs occurs. The risks of concurrent pregnancy have been already emphasised.

Whilst the operation for removal was associated with a high mortality it followed as a matter of course that the alternative miseries attendant upon the presence of fibroid disease were ignored or depreciated as much as possible. With the decrease of danger these may be estimated at something more like their actual value and importance. In the early stage there are aching, weariness, and pain which is constant, varied by pain which is very acute just before each period. The patient must give up her business or profession whilst the period lasts, for she must spend that time on a couch or in bed. Worst of all she is for ever dribbling urine. Think what that means. The pressure on the bladder, or if the growth is posterior, the dragging upon the vesical neck is persistent. Whenever the bladder contains a little urine there is an insistent desire to evacuate it. If that desire cannot be complied with the urine escapes. During the day there is a penetrating urinous odour about the patient which, fight against it or disguise it as she will, forces her to become isolated. She cannot spend a few hours at a concert, at church, or at the theatre; she cannot take part in any society, owing to this wretched infirmity, which constantly reminds her of her merely animal nature and debars her from the natural pleasures of her more intellectual tendencies. As time goes on and the enlarged uterus rises into the abdomen this will improve, but only if the fibroid is interstitial or submucous. If, on the contrary, it should grow into the broad ligament this symptom is often intensified and increased. Suppose the former happens the urinary trouble is replaced by the exaggerated loss of blood. In any case this happens. The periods are not only more copious; they are prolonged. Naturally two or three days only in duration, they last now four, five, six, eight, or ten days, checking a little one day to gush more profusely the next. Nor is this all. Originally recurring once in four weeks, they now return every three weeks or even every fortnight, whilst the period of freedom, during which a little strength might be regained, becomes shorter and shorter. One of my patients who was possessed with the old ideas about fibroids and who believed that operation meant death passed six months without having more than one day free at a time from hæmorrhage.

Hæmorrhage which does not kill loses after a time its terrors for the medical attendant; but consider what persistent hæmorrhage lasting for months and years means to the patient. She is like a business man who attempts to carry on his business with little or no balance at his bankers—every slight call upon his resources brings him to the verge of bankruptcy and keeps him in a perfect fever in order to maintain his hand-to-mouth existence. So with a fibroid patient. As long as she can be absolutely quiet, as long as no sudden or even moderate calls are made upon her strength, so long she may live a vegetative life. But what a life! Anything out of the ordinary routine and she pants for breath, faints, collapses. Even the confined, mewed-up life of a confirmed invalid becomes at last almost too much for her. Her white lips, pearly conjunctivæ, puffy eyelids, sunken eyes, and fleshless limbs show unmistakeably that she has but just enough of blood to suffice for the most elemental needs. Her muscles waste, partly for want of exercise partly for want of nourishment; every movement, every effort is a struggle, whilst her nervous system becomes irritable, emotional, its action irregular and altogether inefficient. If she is a woman with but little will she yields in the unequal struggle, becomes captious and peevish, and a misery to herself and to everyone around her. If she is of better fibre she undergoes a daily martyrdom to which the short, sharp agony of the mediæval saints was but a trifle. And it is when after months and years of patient and almost hopeless endurance she has reached this stage that surgery is at last invoked. Can it be wondered at that sometimes surgery is, under such circumstances, followed by fatal results? Is it not more to be wondered at that in so many cases success is achieved and the patient is at last freed from the daily drain and succeeds in recovering health and strength? What different prospects would surgery have if it were allowed to act whilst yet the patient's strength were unsapped, whilst yet there was a reasonable amount of blood in her body? Since all fibroids, however large, must at one time be small, and since the risks of removal increase *part passu* with the size of the tumour and the amount of blood lost, it would seem that now we have arrived at this: so long as fibroid tumours give rise to no marked symptoms and show no tendency to enlarge they may be ignored; if, however, they are definitely increasing in size it is wiser to remove the entire uterus, leaving all the ovarian tissue possible, whilst the tumour is yet fairly small. In this way the risks of the operation will be minimised as far as possible, the patient will be in the best condition to ensure success, and will be saved most of the miserable but inevitable results of this disease.

Manchester.

ON THE TREATMENT OF VARIOUS INFLAMMATORY PROCESSES BY THE EXTERNAL APPLICATION OF ALCOHOL.

By THEODORE ZANGGER, M.D.,
LATE ASSISTANT PHYSICIAN, UNIVERSITY HOSPITAL, ZÜRICH.

THIS treatment came under my notice in 1896 through a paper written by Dr. Salzwedel in the *Berliner Klinische Wochenschrift* who warmly recommends it for the treatment of whitlow, lymphangitis, phlegmon, incipient abscess, &c. He states that in many cases if the treatment is commenced soon enough the inflammatory process is arrested and disappears within forty-eight hours and that in all the cases in which suppuration is unavoidable the suppurative process is promoted and the forming abscess is more localised and thus the time of healing is shortened. Dr. Salzwedel claims that the alcohol vapours enter the skin and act as direct disinfectants on infected tissue. Other medical men in Germany have since tested these bandages and also recommend them. I have used them for the last two years in all suitable cases with favourable results.

The application must be made with care if we wish to be sure of the result. The inflamed part is washed with soap and water—if necessary with ether—dried, covered with some gauze (to prevent the cotton-wool from adhering to the skin), and then a layer of from ½ in. to ¾ in. of cotton-wool is bound round the part by means of a gauze bandage. The whole is saturated with a strong solution of alcohol. In Germany and in Switzerland we use 96 per cent. alcohol—the spiritus alcoholisatus to avoid the expense of absolute alcohol; the spiritus rectificatus (86 per cent.) of the British Pharmacopœia will serve the same purpose. Over this bandage, well saturated with the rectified spirit of wine, but not so *that it drips*, a cover of gutta-percha paper is fastened by means of a gauze bandage so that it overlaps the bandage by one inch on every side; this gutta-percha paper must have small holes cut in it at intervals of about an inch. These holes are easily made by folding the paper from six- to ten-fold and snipping off the edges. The whole process takes less time to execute than to describe. This bandage is removed every twelve or twenty-four hours, according to circumstances—the severity of the case, the pain, the fever, the rapidity of evaporation, &c. The same gutta-percha paper can be used two or three times if cut large enough, as the alcohol makes it shrink. It is very essential that the bandage should reach an inch or two beyond the inflamed part and that the gutta-percha paper should itself reach beyond the bandage by an inch, also that holes should be cut in the gutta-percha paper to ensure evaporation. These bandages are often too circumscribed if the inflammation covers a great area; if limited to the limbs the attendants or relatives of the patient can renew them alternately with the medical attendant. The expense of these appliances is inconsiderable and they can therefore be used in the out-patient department of hospitals.

---

[12] Brit. Med. Jour., Feb. 11th, 1893.
[13] Petersburger Medicinische Wochenschrift, No. 19, 1896.

The bandages have in most cases afforded me entire satisfaction so that I think it will be instructive if I publish some notes in full, taking only one example in each category. I have seen failure only in a few cases, when either the application was not made correctly or for particular reasons was not continued long enough.

Whitlow.—The usual treatment with either cold, tepid, or hot applications of watery solutions of some antiseptic or other, such as boric acid, acetate of lead, or alum solutions, or even solutions of mercury perchloride, does not give as satisfactory results as these alcohol applications. It is extremely doubtful whether the antiseptics are absorbed by the skin at all, thus we can only rely on the effect of the watery application. Commencing whitlows subside under alcohol and disappear. The pain is alleviated rapidly and definitely in the majority of cases. In progressive cases the inflammation confines itself to quite a limited area, the secondary inflammatory symptoms—œdema and lymphangitis—vanish, suppuration is localised and at the same time promoted, the deep-seated abscess tends to burst outwardly instead of progressing to the interior, and incision at the right moment with a couple of days' after-treatment usually effects a cure.

CASE 1.—The patient, aged twenty-five years, pricked herself with a rusty nail on April 19th, 1898. There were pain and swelling of the corresponding finger stretching up the dorsum of the hand and the forearm. An alcohol bandage was applied on the evening of the 20th and the patient passed a good night and had hardly any pain. On the 21st the wound which was on the fourth finger showed some yellow secretion. The third and fourth fingers of the right hand were greatly swollen and red and the dorsum of the hand was still swollen. Alcohol bandages were applied in the morning and at night. The patient passed a good night on the 22nd. Swelling was much less and there was no pain. Bandages saturated with 1 in 2000 *corrosive sublimate* were ordered. The patient returned in the evening in great pain and with increased redness and swelling and wanted an alcohol bandage for the night which was accordingly applied. She had a good night. On the 23rd there were more swelling and redness, but the wound was healing. Under daily application of alcohol bandages the swelling disappeared altogether in three days. A small abscess formed round the wound after incision, but it healed under the application of ointments.

Lymphangitis.—Generally the inflammatory process is arrested within forty-eight hours. Two years ago I had occasion to treat myself for lymphangitis of the left hand due to a tiny abscess under a finger-nail. Sublimate baths having failed to give any relief or to prevent the increase of the inflammation I applied an alcohol bandage with the best results. The pain disappeared in half an hour and the swelling and redness of the hand in thirty-six hours and then the abscess under the finger-nail was cured by removal of half the nail and local antiseptic treatment.

CASE 2.—The patient pricked himself on the cheek with a rusty pen on Nov. 23rd, 1896. When the patient was seen on the 24th there was a slight wound on the cheek an inch from the angle of the mouth with infiltration of the size of a hazel-nut round it. Boric acid and sublimate compresses were used. Most intense pain caused a sleepless night. On the 25th the patient was in bed and his temperature ranged from 102° to 103° F. Alcohol bandages were applied in the morning and at night. He slept almost all night, the temperature being normal on the 26th. Red lines of lymphangitis extending from the wound to the ear were noticed. There were swelling of two glands in front of the ear and slight neuralgic pain in the corresponding ear. The infiltration was then of the size of a walnut, hard and non-fluctuating. The alcohol bandages were continued morning and night. In the evening the patient felt quite well and was up on the 27th. He was dismissed on the 30th, the swelling having subsided. The latter ultimately disappeared under the use of an iodine ointment.

CASE 3.—This case illustrates the prompt action of the application of alcohol in cases of insect bite. The patient was twenty-five years of age. He was bitten on the back of the hand by a cattle-fly on August 2nd, 1898. On the 3rd there were two small white dots on the back of the right hand. There were heat, redness, and considerable swelling of the hand and forearm and lymphangitic lines up to the axilla. There were several swollen glands in the axilla. The temperature was 99·5° F. Intense pain of the whole arm was experienced. Alcohol bandages were applied up to the elbow. In the evening the swelling had increased but the pain was less. On the 4th the hand and arm were swollen to double their normal size and the glands in the axilla were very sensitive. The patient had had a fairly good night. The temperature was normal. Alcohol bandages were applied morning and night. On the 5th the swelling and the pain rapidly disappeared so that the patient was dismissed with his arm in a sling. On the next day the sling was dispensed with.

Localised furunculosis.—This condition is amenable to the treatment. I bear especially in mind the case of an anæmic boy, aged ten years, who resisted antiseptic treatment for six weeks, but immediately improved and was definitely cured by nightly applications of alcohol.

Sycosis can be similarly treated without inconvenience to the patient and a medical friend of mine, a dermatologist, is well contented with this treatment.

CASE 4.—This case is one of acute glandular inflammation after measles. A boy, aged four years, had morbilli in September, 1897. He was never quite well, but pale and languid. Sudden fever came on on Oct. 18th, the temperature reaching 102° F. On the 19th the patient seemed very ill, with furred tongue, great restlessness, and whining voice. The temperature was still 102°. The submaxillary glands and the glands in front of, and behind, the sterno-cleido mastoid muscles were much enlarged and were painful to touch, especially on the left side. There was no throat or ear trouble. No source of infection other than the previous attack of measles could be traced. Wet bandages to be changed every two hours were ordered and 3 gr. of phenacetin at night. On the 20th the temperature was 101° to 102°, but there was less pain. The patient had perspired freely. Short baths of 92° twice daily were ordered. On the 21st the temperature ranged from 102° to 103° and the pain had increased greatly, the patient not having had a moment's freedom from it all night. The swelling of the glands had greatly increased. Phenacetin failed to relieve the pain. There were general tremor and apathy and the patient could scarcely sit up in bed. In the evening the pain was still intense and only two hours' sleep had been obtained out of forty-eight hours. An alcohol bandage was tried. On the 22nd the patient who had slept well notwithstanding a temperature of from 102° to 103° took an interest in his surroundings and wished to get up. The temperature was 102°. The glands were decreasing in size. Alcohol bandages were applied. On the 23rd there was no fever. The glands were smaller and no longer painful. Under alcohol bandages twice a day the glands further decreased in size and the patient was dismissed on Oct. 27th with the injunction to use "iodine vasogen" morning and night. After a week the glands were not to be felt.

I may mention that this treatment, successful as it is in acute glandular swellings, signally fails in cases of chronic, probably tuberculous, swelling of the glands of the neck.

I think the preceding selection of cases will decide many a practitioner to give the alcohol bandages a trial.

Zürich.

TEN CASES OF VAGINAL HYSTERECTOMY.

BY ARNOLD W. W. LEA, M.D., B.S. LOND.,
F.R.C.S. ENG.,
ASSISTANT TO THE PROFESSOR OF MIDWIFERY AT OWENS COLLEGE; ASSISTANT PHYSICIAN TO THE CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, MANCHESTER.

THE operation of vaginal extirpation of the uterus and appendages has been very extensively practised during the last few years, and the results attained have been very satisfactory. Originally introduced as a radical treatment for cancer its scope has been extended to other diseased conditions, such as uterine fibroids if below a certain size, chronic inflammation of the uterus with advanced bilateral disease of the appendages, pelvic suppuration, and, lastly, intractable cases of prolapse. The improvements in technique have been followed by great reduction in mortality. The best results have been obtained in extirpation for fibroids and inflammatory conditions, some operators having published series of 40 and 60 cases without a death. In cancer the mortality has been somewhat higher, especially if the disease has advanced beyond the early stages. It has also been clearly shown that for malignant disease extirpation of the uterus can only rank as a palliative procedure since recurrence sooner or later is almost invariable. There can be little question, however, of the great relief and prolongation of life which is generally afforded by the operation. I have performed vaginal extirpation in 10 cases—in 5 cases for cancer of the uterus (cervix 4, body 1), in 3 for multiple fibroids, and in 2 for chronic inflammatory affections combined in the latter with removal of the appendages. In this series one death has occurred due to intestinal obstruction nine days after operation; all the other cases made rapid recoveries. The notes are briefly as follows.

CASE 1. *Adeno-carcinoma of the body of the uterus.*—The patient, whose age was fifty-one years, was first seen in June, 1896, on account of uterine hæmorrhage which had commenced six months before. She had had one child twenty-five years ago and the menopause came on in her thirty-ninth year. Examination revealed a senile vagina and cervix. The uterus was bulky and retroflexed. No adhesions could be discovered. The sound passed 3 in. and the cavity felt large. The uterus was explored under anæsthesia and small hard masses of growth were removed. Microscopically these showed typical adeno-carcinoma and immediate extirpation was advised. The patient would not, however, at first consent, but later, in October, 1896, she was admitted into a home and extirpation of the uterus was performed. The ovaries and tubes were atrophied and were not removed. The patient rapidly recovered and left the home in three weeks. The uterus on section showed extensive diffuse growth, infiltrating the muscular wall; the peritoneum was healthy. The patient remained quite free from recurrence for twelve months. She then began to feel intense pain in the back and down the left leg and examination revealed a recurrence of growth at the side of the pelvis. A little later she developed enlargement of the lumbar glands and ascites. She then commenced with symptoms of lung trouble, hæmoptysis and cough, the result of extensive secondary growth. She gradually sank and died eighteen months after operation.

CASE 2. *Carcinoma of the cervix.*—The patient whose age was fifty-three years and who had had two children was sent to me by Dr. Arthur Chapman in March, 1898. For two months she had noticed bleeding from the vagina and a month later she commenced to have pains over the right hip. The menopause occurred at forty-three years of age. The vagina was senile and narrow, the cervix was hard, and a mass of growth could be felt in the canal and invading the external os. The fundus was small and the cervix moved freely. Per rectum, however, induration of the right sacro-uterine fold could be plainly made out. The appendages were small. On April 30th vaginal extirpation was performed in a nursing home. She rapidly recovered and returned to her own home in eighteen days. The uterus showed advanced glandular carcinoma commencing in the cervical canal and reaching as high as the internal os. The fundus was healthy. It is in this form that the growth frequently becomes very extensive before causing symptoms and in this instance although operation was undertaken two months after the earliest hæmorrhage lymphatic invasion of the base of the right broad ligament had already taken place. The patient remained quite well for six months but in October last she felt recurrence of pain in the right hip and a small mass of secondary growth can now be felt in the glands at the brim of the pelvis.

CASE 3. *Carcinoma of the cervix.*—The patient, fifty-nine years of age, was seen by me in July, 1898, with Dr. Godson of Cheadle. A month previously whilst exerting herself she had a profuse hæmorrhage. Up to this time she had felt perfectly well. The hæmorrhage became very slight after a few days. She had had three children the youngest of whom was twenty-five years of age and the menopause had occurred at the age of fifty-one years. She looked in excellent health. The vagina was very narrow; the cervix showed an area of ulceration around the external os and felt nodular and hard. The uterus was small and moveable. Per rectum, however, slight thickening of the base of the left broad ligament could be detected. A few days later I removed the uterus at the patient's own home. She made a rapid recovery and at the present time remains in perfect health. The uterus on section showed adeno-carcinoma commencing in the glands of the cervix and being more advanced in the upper parts of the cervical canal. The body was small and atrophied.

CASE 4. *Carcinoma of the cervix.*—The patient, aged forty years, consulted Dr. Percy Cooper in August, 1898, on account of uterine hæmorrhage which had been present more or less constantly for ten months and for the last month she had suffered from very severe pains over the right side of the sacrum and hip and shooting down the right leg. A few days later I saw her. She had had 6 children, the youngest being ten years of age. Menstruation had been regular but at each period the bleeding had been excessive. The cervix was much enlarged by a mass of growth involving both lips and extending posteriorly on to the vaginal roof. The base of the right broad ligament was thickened and the right sacro-uterine fold could be plainly felt. The uterus did not pull down freely with volsella. The body was moveable. It was evident that the growth had extended so much that although removal was possible recurrence must take place before long. The patient, however, suffered intense pain, requiring morphia, and she was otherwise in such good general health that I thought removal would give temporary relief, although operation could not be urged. She decided to have the operation carried out. On Sept. 18th, assisted by Dr. Cooper, I removed the uterus. This was somewhat difficult on account of its large size and of the perimetric thickening on the right side. After taking away the uterus I found a mass of growth lying on the sacral plexus. This I removed carefully, exposing the trunks of the nerves. The patient made a speedy recovery, all pain having ceased. At the present time (January, 1899) she is very well, although occasionally she feels slight pains in the right hip. Recurrence, however, must be anticipated before long. Still the relief given has been very marked.

CASE 5. *Carcinoma of the cervix.*—The patient, aged thirty-eight years, had been ailing for three months from attacks of vomiting and general weakness. She had had four children. She stated that she was fairly well until May, 1898. She then noticed an offensive discharge with hæmorrhage and for a month the bleeding had been very severe. She was anæmic and had lost 2 st. in weight. Examination showed an extensive epitheliomatous growth of the cervix which bled very freely. The uterus was not obviously enlarged and there was no perimetric thickening. Careful examination of the other organs of the body revealed no evidence of organic disease. Vaginal extirpation was performed in the usual way on August 5th. There was little shock and for two days the patient progressed favourably. She then commenced to be sick and this lasted for four days. The temperature remained normal and the bowels acted freely. On the sixth day the sickness became fæcal and no flatus was passed. The pulse now rose to 120. It was evident that intestinal obstruction had supervened, possibly from adhesion of bowel to the stump of the broad ligament. The abdomen was opened. I found that the end of the broad ligament beyond the upper ligature on the right side was necrotic and a coil of ileum was adhering to it. There were no signs of general peritonitis. The coil was separated, but no relief was given and the patient died on the ninth day after removal of the uterus. No post-mortem examination was obtained. In this case I cut the upper ligatures short and drained as usual with gauze. Owing probably to the debilitated condition of the patient the usual adhesions occluding the peritoneal cavity did not form, and I believe the upper end of the broad ligament then became infected from the vagina. It is in these cases wiser to leave all the ligatures long and to draw the stumps of the broad ligaments well down into the vagina.

Case 6. *Multiple fibroids; prolapse; hypertrophy of the cervix.*—The patient, aged forty-five years, unmarried, was sent to me by the late Dr. Hugh Moss in February, 1897. She had suffered severely from sacralgia for six years and for some months had been unable to go about. The pain was not relieved by rest. She complained also that the womb came outside the vagina.' Menstruation had been profuse for the preceding two years, lasting seven days. On examination the cervix was found to lie outside the vulva, due to hypertrophy of the vaginal portion. The uterus was very bulky and a firm, rounded mass filled up the pelvis reaching to the promontory of the sacrum. The sound passed forward 4½ in. and a mass was also felt in front of the uterus. The diagnosis of multiple fibroids was made. Some months later, as she became quite incapacitated, I advised total removal of the uterus. The patient was admitted to a nursing home in February, 1897, and a few days later the uterus was completely removed per vaginam. The operation was tedious owing to the bulk of the tumours which formed a mass of the size of a fœtal head. The appendages were healthy and were not removed. Since that time the patient has been well and able to carry on a business. The uterus showed great hypertrophy of the vaginal portion of the cervix which measured 2½ in. in length. A large fibroid occupied the posterior wall of the uterus and similar tumours were present on the anterior wall and the fundus uteri.

Case 7. *Multiple fibroids; cystic ovary; pelvic peritonitis.*—The patient, aged thirty-six years, was unmarried. She had suffered from constant pelvic pain for ten years. This was felt chiefly in the back and iliac regions and was much aggravated during the menstrual periods. Menstruation began at the age of sixteen years. It was of the twenty-eight-day type, lasting from three to four days. Pain was not a marked feature during the first years, but it had gradually become more severe. She was quite unable to make any exertion and was confined to a couch. No history of infection could be obtained, but she had been under treatment for many years without receiving any marked relief. The vagina was small, the cervix was high up, and the uterus was antiflexed. The fundus was pushed to the right side by a firm mass in the left broad ligament. The right ovary was enlarged, prolapsed, and adherent. There were also numerous peritoneal adhesions. As all previous measures had failed I advised total extirpation of the uterus. This was performed in December, 1897. The mass felt on the left side was an intra-ligamentous fibroid of the size of a large orange. The right ovary showed chronic inflammation and was cystic; it was therefore removed. The left ovary and tube were small and apparently healthy; I therefore, with a view of avoiding nervous sequelæ, did not take them away. Convalescence was rapid and uninterrupted The patient left the home at the end of three weeks feeling quite well. Since then she has at times complained of back-ache and right iliac pain, much worse on walking, although nothing abnormal can be felt and the scar is not painful. There is, I believe, in this case a nervous element, and it illustrates the fact that even after a radical operation pelvic pain may persist in women of a neuralgic type.

Case 8. *Uterine fibroids; pregnancy terminated by abortion twice.*—The patient, aged twenty-nine years, was sent to me by my friend, Dr. E. J. Carruthers. She had been married for seven years and had two children living, aged five years and four years respectively. Since 1896 she had been twice pregnant and on each occasion it had been necessary to induce abortion on account of a fibroid tumour in the left broad ligament. This rapidly enlarged during each gestation, causing intense pain and obstructing the lower segment of the uterus. In July, 1897, when I saw her she was again three months pregnant. She had been in bed for six weeks with severe pain in the left side of the abdomen. On examination an irregular mass was felt reaching up to the umbilicus. The body of the uterus could be made out lying to the right and above the tumour. Per vaginam the fibroid mass filled up the left side of the pelvis, displacing the cervix to the right. It was evident that a living child could not be obtained *per vias naturales* and I did not feel justified in advising the patient to wait until full term and then submit to Cæsarean section or to Po operation. I therefore recommended removal of the uterus. The tumour and pregnant uterus were too bulky to permit of removal per vaginam, so I introduced a tent and the next day evacuated the contents of the uterus. A week later as the tumour had much diminished in size I was able to remove the uterus per vaginam. The broad ligaments were thick and vascular requiring numerous ligatures. Dense peritoneal adhesions were found over the posterior wall of the uterus and over the tumour, thus accounting for the severe pain from which the patient suffered so much. The ovaries and tubes were normal and consequently were not removed. The patient made a rapid recovery and returned home in three weeks. Since that time she has been in excellent health. The tumour was an interstitial fibroid growing out into the left broad ligament and involving the whole side of the body of the uterus, the uterine cavity being displaced upwards and to the right. A fibroid tumour also occupied the fundus uteri and a similar tumour was present in the cervix. This case is of special interest since large fibroids at the age of twenty-nine years are very unusual.

Case 9. *Chronic metritis; pelvic peritonitis; old pelvic abscess*—The patient, aged forty-one years, who had had three children, the last of whom was born eight years ago, was sent to me in May, 1896. She complained of constant pelvic pain with severe dysmenorrhœa. The symptoms dated from her last confinement. She was then in bed for three months, her illness resulting in profuse discharge of pus from the bowel. This at the time gave great relief, but she had been a chronic invalid ever since, unable to undertake any active exertion and suffering from repeated attacks of pelvic peritonitis. Examination revealed laceration of the perineum, chronic retroflexion of the uterus, and lacerations and erosions of the cervix. The fundus was firmly adherent in the floor of Douglas's space. To the right of the uterus was a dense mass of adhesions in which under anæsthesia an enlarged ovary and tube could be recognised adherent to the anterior wall of the rectum. Since palliative treatment by rest, tampons, &c., had been persevered in for years without obvious improvement I advised complete extirpation of the uterus and appendages. The patient was admitted into a nursing home in July, 1896, and vaginal extirpation of the uterus was performed. The adhesions in Douglas's space and the anterior wall of the rectum necessitated great care. After removal of the uterus the right appendages were enucleated and taken away. The left ovary and tube were small and as they did not cause pain I left them. The patient progressed very favourably and returned home in three weeks feeling quite well. Two months later she again complained of pain in the regions of the left appendages and I found that there was now an obvious left tubo-ovarian swelling. A few days later I opened up the scar and removed the left ovary and tube. There were no adhesions but a hydro-salpinx had developed in the tube and the ovary showed chronic atrophic inflammation. The patient went home a fortnight later and since then has been very well, although the artificial menopause induced some nervous disturbance and latterly she has suffered from chronic rheumatism.

Case 10. *Chronic metritis; double pyosalpinx.*—The patient, unmarried, aged twenty-four years, was first seen by me in September, 1896, in consultation with Dr. F. W. Warrington. At this time she was suffering from a severe attack of pelvic peritonitis of gonorrhœal origin. She remained in bed for six months, but at the end of that time there was little real improvement. Every attempt at getting up caused a fresh attack of inflammation. In February, 1897, I again saw the patient. Her general condition was excellent. The examination showed that the uterus was very bulky, tender, and acutely anteflexed. The cervix showed abundant purulent discharge. At each side of the pelvis large adherent tubo-ovarian swellings were felt. On the right side a mass was firmly adherent in the floor of Douglas's pouch. In cases of this kind abdominal section has generally been performed, the appendages being removed and the uterus remaining *in situ*. The after-results of these cases have, however, been often disappointing. The diseased uterus remains behind and the pelvic pain with inflammatory thickening of the stumps of the appendages is present In this instance, as both appendages were extensively diseased, I decided that the safer operation and the one more likely to give a permanent cure was the removal of the uterus and appendages per vaginam. On Feb. 18th I performed the operation in the usual way. On opening Douglas's pouch about 6 oz. of dark blood and clots escaped, right ovary and tube were nucleated from dense adhesions. The tube contained 2 oz. of pus; there was also an abscess in the ovary. The left appendages were similarly removed. On this side, however, the adhesions to the sigmoid flexure necessitated great care. The pelvis was now flushed out with sterilised water and the vaginal vault was sutured in the usual way. The patient had little shock and made a rapid recovery. She is now in perfect health and in this instance there have been no nervous sequelæ attributable to the artificially induced menopause.

In these cases the ligature has always been used to control the broad ligaments and I have no experience of the use of clamps for this purpose. It is worthy of note that Doyen and others who have advocated clamp forceps have again reverted to the use of the ligature. There is no doubt that a slight saving of time is effected by using forceps, but it is only exceptionally that this becomes a factor of importance. The bladder having been widely separated the utero-vesical pouch is opened and then an opening is made in the pouch of Douglas. The broad ligaments are now ligated in *sections from* below up. In passing the ligatures I have always used the notched needle as recommended by Professor Sinclair. The ends of all the ligatures are left long. After removal of the uterus the condition of the appendages must be carefully investigated. If they are diseased it is easy to draw them down into the vagina and to form a pedicle which is tied close to the brim of the pelvis. In inflammatory cases great care is required in separating adhesions to omentum and bowel, but after the uterus is taken away these can be readily brought into view and dealt with. If the appendages are high up and a ligament cannot safely be passed a pair of pressure forceps will control the ovarian vessels at the outer border of the broad ligament and these may be removed in twenty-four hours. The cavity of the pelvis is now flushed out with *saline solution and by traction on* the ligatures the whole of the broad ligament can be brought into view and any bleeding point secured. Sometimes, especially in cases of cancer, the cut surfaces of the vaginal wall bleed freely and may require a ligature. The central portion of the gap in the vaginal roof together with the peritoneal edges are now united by continuous or interrupted silk sutures, any prolapse of bowel meanwhile being avoided by the introduction of a small sponge. In this way the raw area on the posterior wall of the bladder is covered over and a smooth peritoneal surface is presented towards the abdominal cavity, thus diminishing any tendency to prolapse or adhesion of bowel *or* omentum. A strip of sterilised, moist gauze is now passed along the ligatures on each side to provide efficient drainage *and the ends of the* threads are cut off short just within the vagina. The vagina is now packed with gauze. This dressing I often leave for four or five days if all goes well. In cancer cases, however, it usually becomes offensive and must be removed earlier. Gauze should be introduced in the vagina for a week. After this time douches may safely be given. The threads become loose and separate from the fourteenth to the twenty-first day. This, however, is often associated with slight pyrexia beginning about the tenth day and the discharge becomes offensive—due to infection of the stump of broad ligament and the silk from the vagina. To avoid this drawback some operators cut off each ligature short after the ends are tied and then close the peritoneal cavity. The silk is then usually absorbed and causes no further trouble. In the one fatal case I cut off the ligatures short and the stump still became infected from the vagina, resulting in adhesion of a coil of ileum. In cases of cancer where the tissue may be infected it is impossible to ensure complete asepsis, and I believe that it is best in these cases to leave the ends of the threads long and to draw the stump of the broad ligament well down into the vagina, passing a strip of gauze above it to provide efficient drainage. If healthy reaction occurs the peritoneal cavity is occluded within thirty-six hours and all danger of infection or adhesion of a coil of bowel is at an end. In removal for fibroids or displacements the ligatures may safely be cut short and then care should be *taken to completely* close the peritoneal cavity, leaving only a small opening at each side for the introduction of a gauze drain. If the ligatures are cut short it is specially important to suture the vaginal vault, since local infection of the stump of the broad ligament from the vagina is very likely to occur, leading to troublesome convalescence and in some cases to obstruction of the bowels. It has not been shown, however, that there is any special disadvantage in leaving the end of the threads long, although local infection almost invariably occurs. The threads always come away, and since no foreign material is left behind a sound scar inevitably results.

Manchester.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PROTRUSION OF THE SMALL INTESTINE CAUSED BY LACERATION OF THE ABDOMINAL WALL; RECOVERY.

BY J. R. JENKINS, M.D. ABERD.

ON Sept. 22nd, 1898, I was called, with Mr. William D. Jones and Mr. T. G. Jenkins, to see a patient, aged twenty-two years, who had met with a bicycle accident. It appeared that he was "coasting" down a slight incline and at a turn in the road collided with a pony-cart driven in the opposite direction. The right or off shaft of the cart struck the cyclist on his right thigh and gliding upwards over the groin penetrated the abdominal wall tearing this open to the extent of about 7 in. He attempted to get up *from* the ground but at once discovered that he had a protrusion of bowel. He felt faint and was very sick, but did not lose consciousness. He was picked up by the occupants of another carriage coming up in a few minutes and conveyed to his destination, a mile off, and there put to bed.

We found the patient excited, just recovering *from the* effects of the shock he had *experienced.* He begged for chloroform which we very shortly administered to him and then proceeded to examine the seat of injury. We found a protrusion of the small intestines to the number of six or seven coils and these forced out to an extent of 5 in. It seemed that the shaft had entered at the inner and upper point of the right inguinal region, *tearing* the structures upwards to the extent of 3 in. and downwards nearly to the symphysis pubis, fully 4 in. We attempted to return the bowels but that we found to be no easy matter owing to the much distension of the bowels and a tight grip by the wound and it was not until I made a deep incision through the median edge of the wound that we were able to commence the return of the protruded bowel. Owing to the overlapping form of the wound internally it proved quite impossible to return and replace the bowels without such incision, but with the altered form of the tear we had no great difficulty. There was no scratch or injury to the intestines so that after due antiseptic treatment they were replaced coil by coil. The wound was brought together by a dozen wire *sutures* and *iodoform* was freely applied. A support by a sufficient pad of Gamgee wool and a firm bandage over all completed the operation.

The patient soon recovered *from* the effects of the chloroform which he had taken fully for upwards of an hour. He was given 1 gr. of opium and this was continued every four hours for the first two days and at longer *intervals* up to the fifth day. The sutures were removed one by one, the first on the fourth day; the temperature had then risen to 101° F., the highest recorded. The last suture was *removed* on Oct. 4th (the twelfth day). With the exception of the instance above recorded the temperature was normal throughout. Retention of urine gave trouble for *seven days.* There was no action of the bowels for five days when an enema was administered with the desired effect. No natural action of the bowels took place until Oct. 13th (the twenty-first day). The patient was able to be dressed and to get up *on* the 10th (the eighteenth day). He went downstairs on the 12th and walked out on the 13th (the twenty-first day). He returned to London on Oct. 20th and to Oxford on the 27th, *five weeks from* the date of the accident. By a recent letter he informs me that he is quite well and suffers no inconvenience.

Ruthin.

THREE CASES OF CONGENITAL DEFICIENCY OF BOTH PATELLÆ IN RELATED INDIVIDUALS.

By MAURICE G. PEARSON, M.B., B.Sc. LOND., F.R.C.S. ENG.,
ASSISTANT RAILWAY MEDICAL OFFICER, DE AAR, CAPE COLONY.

THE three cases here related, all in coloured children, illustrate different degrees of this deformity and are interesting as showing the extent to which growth is an element in its cure. The first two are the only children of one father, while the third is the child of his brother and has several brothers and sisters whose patellæ are natural.

CASE 1.—In this patient, a girl aged five months, there is a very noticeable transverse groove in the position of each patella and the finger can be pressed in deeply between the condyles of the femur; the patella itself can be felt as a nodule about $\frac{1}{4}$ in. in diameter; the quadriceps tendon and ligamentum patellæ are narrow cord-like bands. Although of course the child is as yet unable to walk she can extend her knee quite well. The movements and limits of movements are natural.

CASE 2.—A sister of the above, aged four years, has now patellæ which are only slightly smaller than the average. The interesting point about her is the fact that her mother says her knees were as an infant exactly like her sister's, that she was very long in learning to walk, and that even now she cannot walk for long and is "shaky on her legs."

CASE 3.—A cousin of the others, aged seven months. This girl also has very small patellæ but not so small as Case 1. She has also the transverse groove less well marked.

Unfortunately I am not within reach of any skiagraph apparatus. I should be glad to hear from others who have met with these cases whether there is always such a tendency to cure as there has been in Case 2 mentioned above.

Cape Colony.

A NOTE ON A CASE OF SWALLOWING FALSE TEETH.

By J. S. SHARMAN, L.R.C.P. LOND., M.R.C.S. ENG.

EARLY on a Sunday morning a lady swallowed three false teeth attached to a gold plate. At one end of the plate was a sharp hook to fit round the next tooth and at the other two sharp points, the measurement longitudinally was $1\frac{6}{16}$ in. and transversely $\frac{4}{16}$ in. The patient was awakened by a sense of suffocation. She pressed her throat and she stated that she could feel "them go down." There was practically no discomfort and the teeth were passed on the following Friday morning. On the Thursday the Roentgen rays were used but the teeth could not be detected, although from the back one could plainly see through the body, as was proved by placing a small coin over the region of the abdomen. The operator came to the conclusion that the teeth must be hidden by one of the crests of the ilia, as was no doubt the case.

It is worthy of note that experiments on the cadaver have been of little use to test the capability of the stretching of the sphincter of the pylorus. In these experiments a five-franc piece split the sphincter, whereas in the living subject spoons and forks have passed without discomfort. The ileo-cæcal valve and vermiform appendix give more trouble in children than in adults. In most of the text-books very little or nothing is stated besides the various operations as to the treatment of these cases. Rest in the recumbent position and possibly on the right side is desirable, and for diet boiled white of egg, boiled cream, potatoes, rice, and porridge, and if there is any discomfort opium should be administered. In some cases laxatives have been used with success, but this must greatly depend upon the form of the foreign body. In one case where false teeth were swallowed it is stated that oakum, figs, and raisins were given and after a week the body was expelled with the oakum and figs attached to the irregularities of the plate and teeth.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

THREE CASES OF DIPHTHERITIC CONJUNCTIVITIS.

(Under the care of Mr. SYDNEY STEPHENSON.)

IT is now generally recognised that the true criterion of the diphtheritic nature of a membranous conjunctivitis is the presence of the Klebs-Löffler bacillus, but statistics are wanting as to the frequency of the occurrence of this micro-organism in conjunctivitis. The value of the antitoxin in diphtheritic conjunctivitis is admitted by nearly all observers[1] and Coppez and Funk[2] consider that the fact is beyond dispute. The failures which have occurred seem to have been in cases in which the bacteriological diagnosis had not been made. The benefit resulting from the hypodermic administration of the antitoxin should not be permitted to cause any relaxation in the local attempts to make the conjunctiva aseptic, for it is far better to prevent the formation and absorption of toxins than to neutralise them after they have entered the body. The presence also in the membrane of other virulent micro-organisms is an important argument in favour of the local application of antiseptics. The use of quinine lotions, strongly advocated by Mr. Tweedy,[3] has not received such general support as we believe it to deserve. For the notes of the cases we are indebted to Mr. C. G. Burton, resident medical officer.

CASE 1.—A girl, aged eighteen months, was taken to the ophthalmic out-patient department of the North-Eastern Hospital for Children on April 20th, 1898. Ten days previously both eyes were noticed to be red and the lids began to swell and discharge matter. She also lost her appetite, became paler, and was feverish at night. On examination there was found to be photophobia in both eyes, the eyelids were swollen, and there was a whitish discharge which was tenacious and stripped off like a membrane. A diagnosis of acute ophthalmia was made. A lotion of perchloride of mercury (1 in 5000) was ordered to be applied six times a day. Three cultivations were taken; one was sent to the Clinical Research Association, one was taken away by Mr. Stephenson, and one was placed in the incubator at the hospital. The Association reported on April 22nd that the growth consisted of Klebs-Löffler bacilli and staphylococci; Mr. Stephenson found Klebs-Löffler bacilli which Mr. Burton also found in his cultivation. The patient was admitted into an isolation ward on April 22nd. On admission she looked very ill and pale and wanted to lie down. She showed marked signs of rickets. The mouth, tonsils, and pharynx were normal in appearance. No physical signs were observed in the chest; there was no cough or stridor. There was photophobia in both eyes; both lids of each eye were swollen and stuck together. The surface of the conjunctiva was red and swollen, there being a distinct membrane which was easily detachable and which left a raw surface. The ocular conjunctiva was slightly congested but the cornea was quite clear. The cervical glands were enlarged as well as the submaxillary and preauricular glands on both sides. The skin of the face round the eyes and the nose was excoriated. There was a slight watery discharge from both nostrils and also an offensive discharge from the left ear; there was no discharge from the vulva. Antitoxin freshly obtained from the Royal College of Surgeons (7 c.c. containing 2000 units) was at once injected into the flank. The eyes were washed every two hours with distilled water. No drugs were given. On the 23rd the temperature remained below 100° F. The urine was acid, clear, and contained no albumin. The knee-jerks were present. A cultivation was taken of the discharge from the nose. On the 24th the eyelids were less swollen and the discharge was less, but fresh membrane still formed during the night. On the 25th no growth had taken place from the cultivation of the discharge from the nose. There was less photophobia but fresh membrane still formed. On the 26th 1000 units of antitoxin were injected. The temperature remained normal and the urine was free from albumin. On the 28th an erythematous rash was visible on the abdomen especially round the injection wound. The patient's general condition had much improved and she now sat up and talked. There was less photophobia. No membrane formed on the 28th, but there was still a discharge of mucus. On May 1st the child had further improved. The antitoxin rash had disappeared. The inflammation of the eyelids was still present and was now thought to be due to other than the Klebs-Löffler bacilli; the local treatment was altered, nitrate of silver (10 grains to 1 oz.) being painted on the conjunctiva once a day and the eyes washed with a lotion of perchloride of mercury (1 in 5000) every three hours. On the 7th the eyes were free from any discharge, but the lids were thickened and the patient had a small amount of photophobia. She was kept in the hospital in order to improve her general condition and was given medicine for the first time. On June 15th she was discharged quite well. The eyes were quite normal and her general condition was much improved, but she was still a weakly infant. The knee-jerks were present all the time that she was in the hospital and *no signs of paralysis* were observed.

[3] THE LANCET, Jan. 24th, 1880.

CASE 2.—A boy, aged three years, was taken for the first time to the ophthalmic department of the North-Eastern Hospital for Children on April 6th, 1898. The left upper eyelid was swollen and red and overhung the lower lid. There was a thin muco-purulent discharge with glutinous material stretching between the lids when the latter were opened; some easily detachable membrane was on the palpebral conjunctiva. Cultivations were taken but the case was at once diagnosed as one of diphtheritic conjunctivitis and the patient was immediately admitted into an isolation ward. It was stated that the left eye began to be affected five days previously but that otherwise the patient had been in very good health. There was some infiltration on the outer side of the cornea. Small impetiginous spots were present on the forehead (? diphtheritic). The cervical glands on both sides of the neck were enlarged and the left preauricular glands could be felt. The patient seemed to be quite well. The temperature was 99° F. and the pulse was good. The throat, nose, and larynx were normal. No signs in the chest were noted. The urine was acid, clear, and contained no albumin. The left eye was washed with a solution of perchloride of mercury (1 in 3000) every four hours and an aseptic pad was kept over the eye. Antitoxin from the Royal College of Surgeons (7 c.c. in 2000 units) was injected into the right flank. The eruption of the face was treated with a dilute ointment of ammoniated mercury. On the 8th the patient ate and slept well; the temperature remained normal. The eyelid was less swollen and there was less discharge, but still a distinct membrane could be stripped off and the membrane gradually formed again in a few hours. The urine was found to contain a trace of albumin. On the 12th the patient's general condition was good. There was a slight discharge and a slight membrane still formed. The impetigo of the face was cured. On the 15th no membrane formed, but there was still a sticky discharge. The lids were not swollen and the cornea was quite clear. The urine was normal. On the 22nd the patient was sent home. His eyes looked normal; a very slight discharge was noticed on his arising in the morning. The urine was normal and the knee-jerks were present. On the 27th he was attending as an out-patient; he had had the eyelids painted with a solution of nitrate of silver (10 grains to 1 oz.) every day. Some blepharitis ulcerosa of the left upper lid was present but otherwise he was in very good health. On May 24th the patient was quite free from discharge, the knee-jerks were present, and no symptoms of paralysis had developed.

CASE 3.—A girl, aged eight months, attended the ophthalmic department of the North-Eastern Hospital for Children for the first time on July 19th, 1898. There was a history of swelling and redness of the left eye noticed seven days previously, photophobia and discharge occurring three days later. She had been feverish and seemed very ill for two days before attending at the hospital. From previous experience Mr. Burton at once admitted the child to the isolation ward and took three cultivations of the discharge. On admission the child was very pale and seemed to be very ill. The temperature was 99·6° F. and the pulse was feeble and rapid. The left eyelids were swollen and red; a thick glutinous discharge on the palpebral conjunctiva was seen on opening the lids which were stuck together. The cervical glands on both sides were enlarged and the left preauricular gland could be felt. The throat, mouth, and nose were normal. There was no discharge from the ears and nothing was seen on the vulva. 7 c.c. of antitoxin (2000 units) were injected into the right flank. The left eye was washed with distilled water only, no drugs being given, and the eye was carefully bandaged with an aseptic pad. On the 20th the child still seemed to be very ill. The temperature ranged between 99° and 101°. The lids of the left eye were swollen and red and some muco-pus was discharged from the palpebral fissure. The lids could be easily everted and the palpebral conjunctiva was concealed by a thick greyish membrane leaving a smooth surface which did not bleed. The urine was acid, clear, and contained a small amount of albumin. Klebs-Löffler bacilli were reported to be present in the cultivation which had been sent to the Clinical Research Association; they were also found by Mr. Stephenson on his agar cultivation; and in the cultivation grown at the hospital were found Klebs-Löffler bacilli and staphylococcus citreus. On the 22nd membrane still formed on both lids but was easily stripped off, leaving the conjunctiva below smooth and red but not bleeding. The urine contained a trace of albumin. The knee-jerks were not obtained. The temperature was now normal and the child's general condition had much improved as she took her food well and slept most of the day. On the 23rd membrane still formed. She could open her eyes well. The knee-jerks were both obtained and were probably present on the 22nd. On the 24th no membrane formed. The palpebral conjunctiva was thick and red; there was very little discharge. The cornea was clear. The left preauricular gland was still enlarged. The urine was normal. On August 3rd the patient was sent home. The discharge had quite stopped, the eyelids looked normal, and the child was quite well. The urine was normal and the knee-jerks were present. On the 31st the eyes had remained quite well and no signs of paralysis had developed.

Remarks by Mr. BURTON.—1. *The frequency of the disease.* During the past year about 200 cases of conjunctivitis have been treated in the ophthalmic department of the North-Eastern Hospital for Children; 6 of these have been found to be chiefly due to the presence of Klebs-Löffler bacilli—i.e., 3 per cent. This percentage is probably too high; but if every case of conjunctivitis had cultivations taken it would probably be found that the specific organism is present in at least 1 per cent. 2. *The danger of non-recognition of the disease.* There is no doubt that the discharge from the eyes of these cases is capable of setting up severe laryngeal diphtheria and as a rule no care at all is taken by hospital patients. The mother frequently uses her own handkerchief to wipe the discharge from the eyes of the little patient and at other times the noses of the other little ones of the family. These poor children always sleep two and sometimes three in a bed and use a common towel even at school. 3. *The difficulty of diagnosis.* The only pathognomonic sign is the presence of the diphtheria bacilli. The formation of membrane occurs frequently in cases of conjunctivitis when there is no suspicion of the case being diphtheritic. The underlying conjunctiva is red, raw, and rough, although this is not always so in diphtheritic and is sometimes so in non-diphtheritic conjunctivitis. The enlargement of the preauricular glands, though present in these cases, may not be due to the diphtheria bacilli. Diphtheritic paralysis has occurred after simple diphtheritic conjunctivitis and would make the diagnosis conclusive. 4. *Type of the disease.* Although these three cases appear to belong rather to the "croupous" than the diphtheritic variety of conjunctivitis, nevertheless as the specific organism was always present they fully deserve the name of "diphtheritic." 6. *Treatment.* Although in these cases antitoxin was the only treatment adopted in each case other bacilli were present besides the Klebs-Löffler, so some local treatment should be added, such as washing the lids with a solution of perchloride of mercury. If the discharge persists cauterisation with nitrate of silver should be tried. The greatest care should be taken that the discharge is not conveyed to the non-affected eye or to the mouth or vulva. 6. Prophylactic treatment. If by chance any diphtheritic membrane should be coughed by a patient into the eye of a medical man or of a nurse antitoxin should be given and the lids should be washed frequently with a solution of mercury and painted with a solution of nitrate of silver (10 grains to 1 oz.). For permission to record the notes of the above cases I am indebted to Mr. Stephenson.

VICTORIA GENERAL HOSPITAL, HALIFAX, NOVA SCOTIA.

A CASE OF BRADYCARDIA OCCURRING IN A YOUNG MAN; NECROPSY.

(Under the care of Dr. C. DICKIE MURRAY.)

DR. MURRAY'S very striking case of bradycardia is well worthy of being recorded. The complete absence of any effect from the administration of drugs which usually accelerate the action of the heart is very noticeable. The slowness of the pulse was not so marked as has been described, for F. V. Boulioubach of Moscow is quoted in the *Universal Medical Journal* of Philadelphia (September, 1895) as having observed one case in which 14 and on some occasions only 8 heart-beats were counted in a minute; though in such a case it is not improbable that heart-beats were missed. In Dr. Murray's case we are not told what was the condition of the peripheral vessels

A seaman, aged twenty-one years, was admitted to the Victoria General Hospital, Halifax, Nova Scotia, on Nov. 9th, 1897, being one of the crew of a ship which was wrecked off that port on Nov. 7th. He complained of pain in the præcordial region, dizziness, dyspnœa, and occasional convulsive seizures. His father was living and well, his mother died from cancer, and he had two sisters who were well. His family history was otherwise unimportant. He had been at sea for the previous five years and had been constantly exposed to rough weather; he said that he was scarcely ever dry. He had used alcohol and tobacco freely. There was no history of venereal disease. He had suffered from an attack of scarlet fever in childhood and about five years before admission to the hospital he was confined to bed for a fortnight by an attack of pain and soreness in the knee-joints and ankle-joints; the pain and soreness disappeared under treatment and were probably rheumatic. He dated his present condition back to four years ago when one day after running he was seized with a sudden pain over the heart, followed immediately by severe dyspnœa which continued for some days so that he was unable to work. The pain over the heart was followed by a sensation as of something bursting. His condition improved and he was able to return to work, but he had been troubled ever since by more or less pain and dyspnœa which were increased by exertion and were sometimes worse after eating. Since the first attack he had had several convulsive seizures which occurred suddenly with little or no warning. During these attacks he was quite unconscious and was told that he kicked and screamed for some minutes. He felt somewhat weak for two or three days following such a seizure. For the past year the pain and dyspnœa had been getting worse, so that he had not been able to do much hard work.

On examination the patient was found to be a well-nourished and very muscular man about 5ft. 4in. in height and weighing 130lb.; he was bright and intelligent, his cheeks were ruddy, and he had no characteristic morbid appearances. All the systems except the circulatory were normal. As regards the circulatory system there was pain in the præcordia with dyspnœa and dizziness. A faint feeling was present which did not so much seem to depend upon exertion as upon his assuming the upright position. The dyspnœa often prevented him from sleeping at night. Sometimes the præcordial pain was increased by eating and was accompanied by a feeling of distension in the epigastrium. The cardiac impulse was hardly perceptible to the eye, but on palpation it was found to be slightly displaced downward and to the left; it was not strong but was felt to be longer or not so abrupt as the normal impulse. This impulse occurred about 26 or 28 times a minute. On percussion the cardiac dulness was found to be enlarged downwards and to

On auscultation a loud rough murmur was heard with the cardiac systole. This murmur was audible in the mitral area and slightly in the axilla, but was not transmitted to the back. It was also heard in the tricuspid area and over the whole of the heart, but loudest in the aortic and pulmonary areas, where another murmur was also heard immediately following the systole but not quite so loud as the systolic bruit. The murmurs could be heard along the carotid and subclavian vessels. The radial pulse was fairly strong and regular but somewhat delayed, occurring from 26 to 28 times a minute. There was no cyanosis or œdema or any abnormal condition of the superficial vessels.

Various drugs were administered from time to time with the view of accelerating the pulse-rate. Among those tried were alcohol which was given in moderate quantities during the whole of his stay in the hospital, atropin which was given at the suggestion of some members of the branch of the British Medical Association before whom he was exhibited, nitro-glycerine, strychnine, and digitalis, but none of these had the slightest appreciable effect upon the pulse-rate. One afternoon under the influence of laughter and excitement his pulse registered 42 for a short time. The cardiac murmurs were verified by numerous medical men and he was exhibited before, and examined by, members of Dr. Murray's class of clinical medicine. On the afternoon of Jan. 1st, 1898, the patient, in company with two convalescent patients, left the hospital grounds and went into the town. They returned to the hospital late at night intoxicated and the patient was very sick and vomited much during the night. The next morning they were discharged from the hospital and the patient went to a boarding-house. On the following morning (Jan. 3rd) he called at Dr. Murray's residence and asked him to prescribe for him as he was feeling very miserable. Dr. Murray suggested that the discipline of the hospital having been vindicated he would give the patient an order for readmission, of which he gladly availed himself. During the next twenty-four hours he was very quiet, but beyond being given a small quantity of alcohol four or five times a day he was under no medical treatment. On the 4th at 12 o'clock, on returning to the ward from the dining-room where he had eaten very little, he suddenly fell forward and in spite of attempts to resuscitate him he expired in about five minutes.

Necropsy.—A post-mortem examination was made by Dr. W. H. Hattie, pathologist to the hospital, and the various organs were carefully examined. No abnormal condition was found in connexion with any organ but the heart and the lungs. The pleura of the left lung showed adhesions extending from the second rib to the base of the lung; these were separable by the hand. The right lung also showed adhesions, but these were not so extensive and were more easily separated. The heart weighed 14 oz.; all the valves were in perfect condition and were free from vegetations. The left side of the heart was hypertrophied and the muscle was hard and resistant; the right side was soft and flabby. The heart muscle was very friable and on being examined microscopically showed evidence of having undergone fatty change of an infiltrative character with possibly some true degeneration. The brain which was hardened in fluid and examined showed no morbid condition.

Remarks by DR. MURRAY.—The case of bradycardia described above presents some features which make it desirable that it should find permanent record in the too scant literature referring to this symptom of disease. The ordinary text-books make but brief reference to this condition and I have found it difficult to get access to any very complete sketch of the clinical history of such cases or of the various pathological lesions usually accompanying them. The case presents several features of more than usual interest—namely: (1) the youth of the patient and his apparently well-nourished and robust condition; (2) the extreme slowness of the pulse which was unmodified by any drug tried; (3) the presence clinically of well-marked and diffuse murmurs which were not accounted for by any valvular conditions; and (4) the discovery post mortem of a degenerated heart muscle. The causes of bradycardia have been classified as follows: (*a*) cardiac alterations—fatty changes, stenosis of the coronary arteries, and presence of other degenerations and tumours of the heart; (*b*) irritative lesions of the central nervous system and vagus and injuries to the spinal cord in the cervical region either the result of trauma or the growth of tumours; (*c*) paralysis of the accelerator nerves and disease of the cervical ganglia; and (*d*) bulbar ischæmia and venous hyperæmia of the medulla by sclerosis of arteries or by compression of the superior vena cava. This case was probably due to the first of these causes, the presence of fatty changes in the heart muscle being the only discoverable lesion. I regret that a careful examination of the cervical ganglia and of the nerve-supply of the heart was not made. The presence of occasional convulsive seizures reminds one that in the case of Napoleon I. Corvisart, his physician, states that the Emperor's pulse was usually 40 and he was subject to occasional epileptiform seizures. A case has been recorded[1] in which the pulse was 40, the apex beat was imperceptible, and a loud systolic murmur was present. On a necropsy being made the heart was found to be hypertrophied and dilated and its walls flabby, but the valves were not affected. The slowing of the blood current must in some way produce the sounds heard.

LEICESTER INFIRMARY.

A CASE OF ENTERIC FEVER WITH SEVERE PERIOSTEAL LESIONS; INJECTIONS OF ANTI-STREPTOCOCCIC SERUM; RAPID RECOVERY.

(Under the care of Dr. ASTLEY V. CLARKE.)

PERIOSTITIS is a well-recognised complication of typhoid fever and two varieties seem to occur; in one the local lesion is caused by the typhoid bacillus, but in the other it is the result of a secondary streptococcic infection. The improvement which followed the injection of anti-streptococcic serum was very striking and if not due to a coincidence it is in favour of the view that the periostitis was the result of the presence of the streptococcus. The value of a bacteriological examination in all such cases can hardly be exaggerated. For the notes of this case we are indebted to Mr. R. H. Fagge, house physician.

A boy, aged thirteen years, was admitted to the Leicester Infirmary on Oct. 2nd, 1898. He had been unwell for eleven days, complaining of headache, pains in the back, and restlessness; there had been no diarrhœa. On admission the abdomen was distended and typhoid spots were well marked; the spleen could not be felt. The tongue was furred and sordes were on the lips. The urine contained a trace of albumin and gave Ehrlich's reaction well. His pulse was 117 per minute and soft and his temperature was 103·4°F. On the 5th a symmetrical papular rash appeared all over the chest and abdomen. The boy grew steadily worse till the 12th, but improved from then until the 16th when pain and swelling were first noticed in the first phalanx of the right ring finger. As the swelling increased an incision was made into it on the 18th, but no pus was evacuated. The patient grew more apathetic and the temperature began again to rise. Further incisions were made on the 22nd and the 26th. On Nov. 4th as the swelling and inflammation of the finger were more marked amputation was performed and it was found that the whole of the periosteum had become separated from the bone, but the metacarpophalangeal joint had not been affected. The patient was still more apathetic and did not seem to understand anything which was said to him. No improvement had occurred by the 10th, for both the mental condition and the local condition were worse. A long incision was made over the metacarpal bone. On the 15th he was still unconscious with much delirium and as the temperature was oscillating between 99° and 102·6° 10 c.c. of anti-streptococcic serum (obtained from the British (now Jenner) Institute of Preventive Medicine) were injected into the left loin. Some local uneasiness followed the injection and the temperature rose to 102°, but shortly afterwards the temperature fell as by crisis to normal, the delirium vanished, and consciousness returned within twenty-four hours. Other injections of 5 c.c. each were given on the 16th, 17th, and 19th, and by the last date the patient was well advanced in convalescence. The hand improved rapidly after the first injection, the swelling and inflammation abating rapidly. On the 22nd raised "urticarial" rings developed around the sites of the injections and by the next day this rash had spread all over the body; it was accompanied by a slight rise of temperature and caused much irritation. From this time the patient rapidly put on flesh and was discharged from the infirmary on Dec. 12th well except for a small granulating surface on the hand. Unfortunately no cultures were taken from the local lesion of the hand when it was first open.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Gonococcus Joint Diseases in Infants secondary to Purulent Ophthalmia.

A MEETING of this society was held on Jan. 24th, the President, Mr. BRYANT, being in the chair.

Mr. CLEMENT LUCAS read a paper on Gonococcus Joint Disease in Infants secondary to Purulent Ophthalmia, with an account of 23 cases. He first drew attention to this disease affecting the joints of infants suffering from purulent ophthalmia in the *British Medical Journal* of Feb. 28th, 1885, more fully on July 11th, and again, with the addition of a third case, on Oct. 10th, 1885, in the same journal. Mr. R. G. Fendick published a case in support of the truth of the observation on Oct. 31st, 1885; but from that time no case seemed to have been published in this country and the authors of text-books were for the most part silent upon the subject. Abroad, however, this hitherto unrecognised joint affection of infants had attracted more attention, and Debierre in France, Zatvornitski in Russia, and Widmark in Germany, had each published a case before the end of the year 1885 in support of Mr. Lucas's contention that the joint inflammation was secondary to, and dependent upon, the ophthalmia. Mr. Lucas had now collected 23 cases, upon which he founded his present communication. The joint disease presented itself in two forms: (1) as a very acute arthritis accompanied with much swelling, tenderness, and redness, strongly suggesting a tendency to suppuration; and (2) as a subacute synovitis, giving rise to a good deal of effusion and pain on movement, but to little or no surface redness. Of the 23 cases collected [illegible] were cases of ophthalmia neonatorum inoculated dur[illegible] labour and 5 were cases of secondary inoculation in other children, the eldest being seven years of age. The ophthalmia generally appeared on the third day after birth. The joint disease showed itself more commonly towards the end of the second or during the third week of the ophthalmia. The knees were the joints most frequently affected, especially the left; any joints might be attacked, but the left wrist seemed more liable than the right; and Mr. Lucas offered as an explanation of the left knee and left wrist being specially selected the fact that they were more exposed to injury in the position in which an infant was usually carried by the nurse. Complete resolution might be anticipated and the inflammation usually ran a course of from three to five weeks. Bacteriological examination had shown that the gonococcus of Neisser was the cause of the ophthalmia and of the joint disease. Where suppuration took place there might possibly be a double infection. In two recorded cases this happened, streptococcus being present in one and staphylococcus in another associated with gonococcus. The affection differed from syphilitic joint trouble in appearing at an early period of life and in its more rapid course.

Mr. N. C. MACNAMARA said that he thought Mr. Lucas had fairly proved the association of joint disease with ophthalmia. He thought that secondary joint affections were due to products of inflammation rather than to organisms, as in several cases of gonorrhœal rheumatism he had failed to find the gonococcus in the synovial fluid. If the gonococcus were the cause he would expect suppuration to occur there as in the urethra. Personal predisposition was certainly an important factor in susceptibility to poisons. Mr. Macnamara thought that other forms of joint disease were traceable to suppuration, believing, for example, that some cases of chronic rheumatic arthritis were due to suppuration round decayed teeth, and the late Dr. Todd held that in some cases it was traceable to vaginal discharge. He thought that ordinary acute rheumatism was due to the absorption of morbid products developed in some way in the alimentary canal. He thought that knowledge of these morbid products would enable sound methods of treatment to be arrived at.

Mr. HIGGENS said that the condition must be very rare as although he had seen a very large number of cases of gonorrhœal ophthalmia in infants he did not recall one in which there was joint affection. He was not convinced that the presence of the gonococcus in the pus signified that the case was one of gonorrhœa.

---

[1] Brit. Med. Jour., Sept. 10th, 1891.

Mr. R. BARWELL said that he had described the association of joint disease with gonorrhœal urethritis in 1861. Rheumatism after scarlet fever was the result of absorption of some poison and he saw no reason for hesitating to admit that joint disease might be an occasional concomitant of suppuration of the conjunctiva. It was rare probably because of the free exit of pus and in the case of gonorrhœa in the adult the freer escape of pus in the female was the probable explanation of the rarity of arthritis as a complication of gonorrhœa in women. Other forms of surface suppuration such as otorrhœa might give rise to arthritis, the arthritis subsiding as the otorrhœa yielded to treatment.

Dr. PYE-SMITH said that the paper helped to settle the nature of gonorrhœal synovitis. The nervous hypothesis was quite abandoned and the pyæmic theory was also disproved as suppuration did not occur unless there was a mixed infection. The difference in type between this form of arthritis in infants and in adults was very instructive particularly in the rapid development and the rapid recovery.

Mr. PEARCE GOULD agreed that the cases described were the same as gonorrhœal synovitis in the adult. He thought that the gonococcus had been repeatedly demonstrated in the fluid from the joint and he did not agree with Mr. Barwell that some morbid product was absorbed, believing that the entrance of this powerful organism produced alike the primary and secondary trouble. Probably the infrequence of joint trouble as a complication of gonorrhœal inflammation in infants was largely due to the fact that their joints were little exposed to injury or strain. He thought the view of Mr. Lucas that the secondary complication subsided in a parallel course with the primary affection was not borne out by general experience or by the cases quoted by Mr. Lucas, in one of which the joint disease did not appear until the ophthalmia had subsided.

Mr. A. E. BARKER did not hold it proved that all cases of joint disease associated with ophthalmia were due to the gonococcus alone but that there was a *mixed infection*, the pyogenic organisms preponderating in severe cases. He thought that the term "pyæmia" might be fairly applied to many cases and among those he would also place the cases of joint disease secondary to otorrhœa spoken of by Mr. Barwell.

Mr. HUTCHINSON asked as to the exact number of cases in which the presence of the gonococcus had been demonstrated. The question of diagnosis from syphilitic arthritis did not come up because in the infant any syphilitic joint disease was due to extension from the periosteum and was of a totally distinct character, but there was a form of syphilitic arthritis which came on later which was nearly associated with interstitial keratitis. The knees were chiefly affected and suppuration was rare. He held out as an hypothesis that in cases of secondary inflammation there was some product of metabolism formed in one tissue and that this gave rise to inflammation in a tissue of similar organisation. Gonorrhœal rheumatism was on this hypothesis more common in males because there was inflammation not only of the urethra but of the fibrous tissues of the penis and it was a poison formed there which gave rise to inflammation of fibrous tissues in the joints. He thought, also, that gonorrhœal rheumatism was predisposed to by a gouty inheritance He would still class gonorrhœal arthritis as a form of rheumatism.

Mr. LUCAS, in reply, said that the gonococcus had been found in a sufficient number of cases to prove the nature of the joint affection. Injury was undoubtedly a predisposing factor, but he was unable to trace a rheumatic diathesis in any of his cases. He thought that gonorrhœal rheumatism was not so very rare in women, but was often overlooked. He insisted that it was extremely important to subdue the ophthalmia at the outset.

MEDICAL SOCIETY OF LONDON.

Appendicitis and Diffuse Peritonitis.—Ureteral Calculus.

A MEETING of this society was held on Jan. 23rd, Mr. J. H. MORGAN, Vice-President, being in the chair.

Mr. CUTHBERT WALLACE read the notes of three cases of Appendicitis and Diffuse Peritonitis. In all three cases there was a local collection of pus which had spread and infected the general peritoneal cavity. In two instances the peritonitis was general and in the third it was confined to the viscera behind the great omentum. The treatment adopted was the same in all. The abdomen was opened and the appendix removed, and then the intestines were turned out on to the surface of the abdomen and cleansed with sterile water while the abdominal cavity was flushed out. Mr. Wallace submitted that this was the most rapid and effectual method of dealing with such cases and of effectually cleansing the abdominal cavity, and he pointed out that it was almost impossible to cleanse the peritoneum while the intestines were *in situ* because the irrigating fluid did not flow out in a steady stream but simply washed the infective material about from one part of the abdomen to another. The incision through the right rectus was best, as the same incision could be used to remove the appendix and wash out the abdomen. All three cases recovered without any complications and were discharged in little over a month.—Mr. CLUTTON congratulated Mr. Wallace on his successful series of cases which he doubted if any other surgeon had been fortunate enough to obtain. He remembered the time some years ago when extraventation was practised, but he did not recall any successful results. But the methods were different. Then the intestines were received in a warm towel, the abdominal cavity was filled not with non-irritating saline fluid but with some antiseptic, and this was removed by turning the patient almost on his face—a proceeding which gave rise to much shock. He asked for more particulars from Mr. Wallace as to the details of his operative procedures. Mr. Clutton observed that in Mr. Wallace's cases the bowels were relieved on the third day. He thought that this had much to do with the good result. There was no doubt that septic absorption took place from the internal surface of the bowel and that evacuation of the contents of the bowel was most desirable. Magnesium sulphate was often talked of but as a rule it was rejected by the stomach. It had been suggested that the salts should be injected into the upper part of the small intestine by means of a hypodermic syringe and if this proved to be feasible it would increase the chances of the patients.—Mr. STANLEY BOYD asked what length of incision Mr. Wallace employed for getting the intestines out. He himself had been deterred from trying extraventation because of the difficulty in returning the bowels and the danger of leakage if they were pricked. Probably incision and drainage would be the best way of dealing with distended gut now. He quite agreed as to the removal of the intestinal contents and a quickly acting purge which would act in a small dose when given hypodermically was much wanted. Absolute cleansing of the peritoneum was not possible and recovery would depend partly on the power of the patient to deal with what was left.—Mr. BRUCE CLARKE said that in a case where there was difficulty in returning the bowel he had incised it, fixing it to the abdominal wall, and closing the opening afterwards. If the patient lived recovery was rapid. He approved of the method of extraventation and of the position of the incision through the rectus, as there was less liability to subsequent hernia.—Mr. W. H. BATTLE said that the symptoms presented by these cases varied and mentioned a patient whom he had recently seen in whom the symptoms at first did not appear to indicate to those who saw him first that the condition was grave. On examination respiration was entirely costal, his pulse was weak, and his face was slightly bluish. An incision was made on the right side of the abdomen and a large quantity of stinking pus evacuated.—Mr. MORGAN agreed with what had been said as to the advantages of extraventation, although the return of the bowel presented great difficulties. Although the abdominal cavity could not be completely cleansed most of the septic material could be removed and in the case of perforated gastric ulcer if the extravasated matter was small in amount and removed early recovery often followed. He thought that the immobility of the abdominal wall was of as great significance as the condition of the pulse and the facial expression.—Mr. WALLACE, in reply, said that abdominal movements might be present when the abdomen was full of pus as in a case on which he operated for ruptured duodenal ulcer. All went well for four days and the movements of the abdomen during respiration were perfect. The patient suddenly collapsed and after death the abdomen was found to be full of pus. As to difficulty in returning the bowel, in his cases there was no distension and there was no difficulty, but in a more recent case he had to resort to puncture and incision. As to the details of procedure he commenced the abdominal incision level with the anterior spine and continued it up for about 6 in. The house surgeon held [illegible] over to one side while the [illegible] they cleansed. The intestine was irrigated all the time with hot sterilised water, saline fluid not being available at the time. When recovery occurred it was very rapid, abdominal movements returning within twelve hours.

Mr. P. J. FREYER read notes of two cases of Operation for Impacted Stone in the Ureter. Case 1.—A patient, aged twenty-three years, had been suffering for nineteen months from renal colic and hæmaturia which was ultimately diagnosed to be due to stone in the kidney. There was a slightly moveable tumour in the region of the right kidney as large as two fists with tenderness on palpation. The kidney was exposed through an oblique lumbar incision 4½ in. long. No stone could be felt, so he opened the kidney through the convex border, passing his finger through into the pelvis when a rush of urine took place. Still no stone could be felt, but on passing a catheter down the ureter an obstruction was found 4 in. from the pelvis. He enlarged the incision 4 in. or 5 in. till he could grasp the stone, which he removed through an incision into the ureter. He did not suture the wound in the ureter, but contented himself with placing a large drainage-tube down to the opening along the back of the kidney, and he partially closed the wound of the kidneys by two stitches. Bloody urine was passed freely in the evening and by both loin and ureter for several days. The patient completely recovered and he left the home five weeks after the operation. He had since operated on this patient's mother, successfully removing several oxalate stones from the pelvis and calyces. Case 2.—A man, aged fifty-two years, had been a patient at St. Peter's Hospital for some thirteen years suffering from multiple stricture of the urethra and symptoms of renal calculus. Exploration of the left kidney in 1895 gave only temporary relief. When he saw the patient in 1897 he was very ill with severe pain in the left loin and hæmaturia. The urine was thick and offensive and deposited about half pus. On Sept. 1st, 1897, he explored the left kidney through an oblique lumbar incision but could find no kidney. No relief followed, so he performed internal urethrotomy on Nov. 18th, but though the operation afforded a free exit for the urine it did not much diminish his other symptoms and the pain in the right loin increased. He continued to suffer very severely and on Nov. 9th Mr. Freyer examined him with a cystoscope under an anæsthetic and detected a long, narrow, rough, pencil-shaped stone projecting into the bladder from the right ureter and this after a little trouble he removed with a lithotrite, and since that time the patient had continued to improve in health although there was still pus in the urine. He briefly alluded to five other instances of stone impacted or encysted in the ureter on which he had operated. In three the stone was impacted at the ureteral orifice projecting into the bladder and felt by the sound (one female and two males).—Mr. BRUCE CLARKE detailed a case which occurred in a woman who had symptoms related to the right kidney. On incising the pelvis through a lumbar incision and introducing the finger no stone could be felt, but a black bougie passed down the ureter met with a stone about 5 in. from the kidney. He incised the ureter and removed the stone. He did not stitch the ureter, but it perfectly recovered its function, as, later, on cystoscopic examination urine could be seen issuing from it. Probably some cases of supposed cystic calculus were due to a calculus impacted in the lower part of the ureter ulcerating through, so that a pouch was formed containing a stone.—Mr. MORGAN commented on the fact that if a calculus were not in the usual place near the kidney or at the lower end it was usually where Mr. Freyer and Mr. Bruce Clarke had found it and he asked whether it was caught where the ureter passed over the brim of the pelvis or the iliac artery.—Mr. FREYER said he thought that a stone might be arrested at any point. It was probably thought that it was especially at the ends because those points were more accessible and so calculi were more often detected there.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Discussion on the Serum Treatment of Diphtheria.

A MEETING of this society was held on Jan. 13th, the President, Mr. EDWIN LEE, being in the chair.

A discussion on the Serum Treatment of Diphtheria was opened by Dr. CHURTON, Dr. BARRS, and Dr. TREVELYAN.

Dr. CHURTON said that it was not always possible to obtain immediately bacteriological evidence as to the nature of a doubtful case and it was therefore necessary to clearly define the clinical evidence—symptoms, signs, and history—which gave the greatest measure of probability that in any given case the specific bacilli were present. He recited the following case as an illustration. A well-nourished boy, aged eight years, under treatment in the Leeds Infirmary for left hemiparesis with complete blindness, apparently due to limited tuberculous disease, was shown to the society on Dec. 2nd. He was rather quickly recovering sight, &c. Next morning, the 3rd, he had a slight headache. At 4 P.M. the fauces and tonsils were rather red; the tonsils were also, perhaps chronically, enlarged. The temperature was 103° F. and the pulse was 140 (previously it had been from 80 to 100). On the 4th the temperature was 101·4° and the respirations were 28. Visible parts of the tonsils were covered with a creamy or greyish-creamy exudation, not leathery or fawn-coloured, not patchy but uniform. At one point, where the left anterior velum rested upon the tonsil, *the cream-white surface of the tonsil exactly resembled exudation from a crypt or follicle.* There was no exudation on the velum. Detachment of a fragment of exudation did not cause bleeding. It was impossible to obtain a bacteriological verdict until next day. There was no albuminuria. The glands at the angles of the jaw were slightly enlarged. The onset though rapid had not been sudden, as it is said to be commonly in ordinary sore-throat. A case of diphtheria complicating enteric fever had been in the ward for a few days a month previously but no case had occurred in it since. 1000 units of Messrs. Parke, Davis, and Co.'s serum were injected and precipitated sulphur was applied to the tonsils by insufflation. On the 5th at 5 P.M. the tonsils were cleaner and showed white spots on a red ground. The white spots were creamy and raised above the red surface but not abruptly. On the 6th it was reported that diphtheria bacilli and staphylococci had been found in the exudation. (The bacilli were also found in a scraping from the tonsil on the 14th; on the 21st there was none.) The boy was apparently free from his new disease; recovery from his original disease was scarcely, if at all, retarded. So far there have been no sequelæ of any kind. The serum produced no urticaria, albuminuria, or anæmia.

Dr. BARRS said that his experience had led him to adopt antitoxic serum treatment in all cases which were clinically recognised as diphtheria. He had seen nothing but good result from its use and he had never seen any ill-effects following its application. The serum should be used in all cases without waiting for a bacteriological diagnosis and used in efficient doses. He thought that the difficulties in making a clinical diagnosis of diphtheria were not so great as had been stated. For practical purposes he held most strongly that all membranous inflammations of the throat should be regarded as diphtheria and promptly treated as such to avoid the chance of fatal respiratory or cardiac failure.

Dr. TREVELYAN first shortly referred to the subject of artificial immunity and its relation to the serum treatment. He then discussed the question of the strength of the serum and the method of expressing it in immunity units. The longer the interval between the time of the infection and the injection of the serum the greater the difficulty of cure and the larger number of units required. The cause of the failure of the serum treatment lay in (1) its too late administration; (2) insufficient dosage, including inefficiency of the serum; and (3) the presence of a mixed infection. In speaking of the severe accidents which had very rarely attended the injection of the serum Dr. Trevelyan did not think that every case should be forthwith injected, but that if the general symptoms were obvious or the local lesion severe or extending then no time should be lost. The proofs of the value of the serum treatment were furnished by (1) statistics and (2) the obviously favourable action upon the symptoms. The numbers which had been treated were sufficiently numerous to warrant the conclusion that the serum treatment was efficient. The disappearance of symptoms of even considerable laryngeal obstruction under the serum treatment was illustrated from a recent case; it constituted one of the most striking instances of the favourable action of the treatment upon the symptoms of the disease. On the other hand, it must not lead to an undue postponement of tracheotomy or intubation. Except in so-called septic diphtheria Dr. Trevelyan did not think that local treatment was desirable as the disadvantages attending a thorough local treatment, altogether outweighed the advantage to be obtained from it in the presence of an efficient general treatment.

After a few remarks by the **PRESIDENT**, Dr. **SPOTTISWOODE CAMERON** commenced the discussion by giving the statistics of the epidemic of diphtheria in Leeds and illustrated them by lantern slides.

Dr **MOUILLOT** (Harrogate) doubted if the mortality of diphtheria was as great as generally supposed. Before bacteriological investigations were made severe cases were diagnosed as diphtheria and the mild ones were not recognised as mitigated examples of that disease. Hence an exaggerated mortality.

Mr. **EXLEY** had treated during 1898 47 cases of diphtheria with 16 deaths (37 04 per cent.). The cases under "ordinary" treatment were 32 with 15 deaths (46·8 per cent.) and the cases under "antitoxin" treatment 15 with only 1 death (6·6 per cent.). Two adults were treated and both recovered. Five cases over ten years of age were treated and all recovered. The death under antitoxin treatment was interesting from the fact that it was the first time that Mr. Exley had used the serum and the administration was delayed until the fifth day. 1500 units were then given and 1500 units twenty-four hours later as the case was severe (nasal). The child rapidly improved on the fourteenth day and sat up in bed for a little time; the patient then became faint and gradually got worse and died on the sixteenth day from the disease. No ill-effects were noted from the use of the serum.

Dr. **ROBINSON** (Low Moor) referred to a severe case in which the symptoms of laryngeal obstruction passed away under the serum treatment. The child, aged nine years, was injected with 3000 units within eighteen hours and made a rapid recovery. Dr. Robinson thought that a short delay was thus justifiable before proceeding to tracheotomy in such cases.

Mr. A. E. **PEARSON**, of the Leeds City Infectious Hospitals, dwelt upon the importance of a bacteriological examination being made in suspected cases before admission.

Dr. **MANTLE** (Halifax) reminded the meeting of the communication he made to the society in May, 1895, when he brought forward three successful cases. He was then a believer in the antitoxin treatment and after a more extended experience he was a greater advocate of it being adopted in all cases. He was, however, convinced that it was wrong to discard local treatment inasmuch as the serum was not a germicide but was merely antagonistic to the poisons manufactured by the bacilli in the throat.

Dr. **BAMPTON** thought that clinically all membranous sore-throats must be treated as diphtheria. But all diphtheritic sore-throats were not membranous.

Dr. **EDDISON** made some remarks chiefly on the question of local treatment.

Mr. **EDWIN ROBERTS** had treated 22 cases of diphtheria during the recent epidemic and 21 of these were injected. The one in which the serum treatment was not employed was moribund when first seen and died in a few hours. Of the remaining 21 2 died. The first of these was injected on the fourth day. He was doing well when a fatal abdominal complication supervened. In the second case, seen on the fifth day, the child was almost pulseless and died the same night in spite of the serum treatment. In those cases injected early and sufficiently the good results were so regularly and constantly observed that one was fully persuaded that the antitoxin treatment was absolutely specific. No other treatment, local or otherwise, was adopted in these cases beyond forced feeding and stimulants.

Dr. **HELLIER** said that he had frequently noticed in cases of diphtheria an early slowness and irregularity of the pulse which were useful in diagnosis. He thought it a mistake to say that whenever there was membranous exudation the case was diphtheritic.

Dr. **CHADWICK** stated that the present success of tracheotomy for "croup" in young children was quite astonishing as compared with former times, the only difference being the simultaneous use of antitoxin.

Mr. **LITTLEWOOD** said that before the days of serum treatment he had performed tracheotomy for diphtheria on 12 occasions. Of these only 2 recovered and 1 died subsequently from cardiac paralysis. Since this time he had operated on 3 most severe cases, all of which recovered under the combined treatment of the antitoxin and tracheotomy.

Dr. **CHURTON**, Dr. **BARRS**, and Dr. **TREVELYAN** replied.

Dr. **TREVELYAN** showed a series of Cultivation and Microscopical Preparations together with Lantern Slides and Diagrams of the Diphtheria Bacillus, and Mr. A. E. **PEARSON** Microscopical Specimens from cases of Diphtheria in the City Fever Hospitals.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Disease of the Cerebellum.—Aphasia.

THE fourth ordinary meeting of this society was held on Jan. 18th, Dr. P. A. **YOUNG** being in the chair.

Dr. **GREIG** showed a man who possessed a Symmetrical Congenital Perforation of each Parietal Bone. The case was reported by Dr. Greig in Vol. XXVI. of the *Journal of Anatomy and Physiology* and is remarkable on account of the rarity of the occurrence. The man had been a soldier for many years and had suffered no inconvenience from the defect. He was slightly under the usual height, somewhat microcephalic, and exhibited in a feeble manner the Mongolian type of countenance. Each perforation was 2½ by 3½ centimetres in diameter and occurred at the postero-superior angle of either parietal bone. They were separated by a bony ridge and the margins were not elevated above the general surface. When the areas were firmly pressed upon the patient suffered from giddiness and flashes of light appeared in both eyes. Professor Turner described a very similar case in the *Edinburgh Medical Journal* of 1865 and Broca recorded two cases; in one of the latter the openings were not so large as in the present case and the second occurred in a negro where the parietal foramina were double. Sir George Humphry described a skull which was in the Museum at Cambridge where these parietal openings were large enough to introduce the finger tips.

Mr. **CAIRD** and Mr. **GUY** showed the case of a man who had suffered from Untreated Syphilitic Disease about five years ago. His condition was miserable as both hard and soft palate were gone as well as the front part of the superior maxillary bone. The cartilage of the nose had been totally destroyed as well as a large part of the upper lip. There was one common naso-pharyngeal cavity. On introducing the finger it was found that the vomer, ethmoid, and turbinated bones were all absent, the finger reaching directly to the cribriform plate of the ethmoid above and to the sphenoidal cells behind. There was no vestige of bone on which to fit an obturator. Mr. Guy had devised a vulcanite obturator which attached to a lip (covered by a false moustache) and a nose were all kept in place by an empty pair of spectacles. The patient's speech which was quite indistinct before treatment is now improving.

Dr. **HARVEY LITTLEJOHN** showed two specimens of Hypertrophied Heart in which sudden death occurred. 1. The first was from a lad, aged twenty-one years, who was found dead in bed and had apparently been perfectly healthy previously. At the ages of seven and fourteen years he had suffered from attacks of rheumatic fever, but for seven years had been in perfect health, bicycling, &c., and being only short of breath after exertion. The heart weighed 28oz. and the hypertrophy was apparently due to aortic and mitral valve disease The auricles were also greatly enlarged. 2. The second specimen was from a man who had been in apparently perfect health when discharged from the Royal Infirmary of Edinburgh but who fell down dead suddenly the same day. The specimen was obtained from the body of an old soldier, aged thirty-five years The heart was one of the heaviest recorded, 3lb (48 oz.).

Dr. **LITTLEJOHN** also showed a rare condition, Partial Rupture of the Heart. The specimen was obtained from the body of an old lady who on getting out of bed one morning felt very ill and had severe pain over the heart; she was put to bed, poulticed, and given peppermint water. She lingered all that day and was found lying dead on the floor next morning. On post-mortem examination a rupture of the internal surface of the left ventricle was found, not perforating the heart, but simply running across the chordæ tendineæ and musculi papillares for about 2 in. This rupture was not caused by the careless handling of a fatty heart, but was actually due to by a pulley attached to a tandem bicycle. He thought the ideal apparatus for the future would be of the Wimshurst type—to drive the tube without coil or batteries. The intense glare rendered the use of the screen unsatisfactory; his screens were covered with celluloid. He used glass sensitive plates exclusively for photographic purposes. On account of the great heat and sandstorms developing was attended with great difficulties, but the results, although photographically imperfect, yielded all the information which was needed by the surgeon. After the battle of Omdurman 121 wounded were brought to Abadieh. Of that number 21 cases could not be diagnosed accurately by ordinary means; in 20 of these the rays showed the presence or absence of a bullet, the remaining patient being too ill to be examined. The method proved valuable in spent bullet wounds, as the possible presence of a foreign body could be ascertained without probing. Accurate localisation was effected in all instances where there was any doubt. His experience showed that probing for an uncertain bullet with its subsequent pain was a thing of the past, that the presence of a bullet could be localised with mathematical certainty in the deeper parts of the body on field service, and that great help could be gained in the case of uncertain fractures.—The President congratulated Major Battersby on the excellent results obtained under extreme difficulties.—Surgeon-Major Beevor narrated some of his experiences on the Indian frontier in which he had applied the Roentgen methods to many hundreds of cases. He found the rays useful in many conditions other than the presence of a bullet and instanced necrosis and undetected partial fractures. In one case a bullet penetrated the liver and lodged in the opposite side of the body. He had found both celluloid films and sensitised paper unsuited for military work.—Professor Silvanus Thompson said that military surgeons should first state the exact shape and size of Wimshurst machine they wanted so that electricians might meet their requirements. He suggested the use of celluloid as an insulating agent and of mica plates for sensitive films.—Mr. W. Webster, Mr. Wilson Noble, Mr. E. Payne, Mr. L. Miller, Mr. J. H. Gardiner, and Major Kilkelly, R.A.M.C., continued the discussion, chiefly from the photographic and electrical standpoints.

MADRAS MEDICAL ASSOCIATION.—A general meeting of this association was held on Dec. 13th, 1898, in the Madras Medical College premises, Dr. Grant being in the chair.—Mr. J. V. Ramasawmynaidu, L.M.S., read a paper on Plague and Vaccination. He first referred to a telegram from the Minister of Turkey to the Secretary of State for India setting forth that the Turks believe that vaccination protects against plague, and then to the opinions of Mr. Haffkine of Bombay and Lieutenant-Colonel Lawrie, I.M.S., of Hyderabad, the former (from statistics taken from Bombay Jail) asserting that plague was not influenced by vaccination one way or the other, the latter asserting that double vaccination is likely to protect against plague. He said that the belief of the Turks in the efficacy of vaccination against plague must have had some justification for its origin. He quoted some old physicians who held the same opinion. He showed that theoretically it was likely that double vaccination may protect against plague on the same principle on which Widal's test for typhoid fever is based. The principle is that serum from man or animal suffering from an active infective fever is detrimental to certain bacteria, that as the result of bacteriological research Mr. A. G. R. Foulerton had shown that glander bacillus was thus influenced not only by serum from a patient suffering from glanders but also by serum derived from a horse immunised against diphtheria. It was not going too far to expect that a subject well protected against small-pox may be immune to plague (by the injurious effect which the serum of the former would have over the bacilli of the latter). He pointed out that the immunity against plague may have been due to the vaccine lymph used in Turkey having become contaminated by plague bacilli.

BOURNEMOUTH MEDICAL SOCIETY.—The ordinary meeting of this society was held on Jan. 18th, the President, Mr. T. F. Gardner, being in the chair.—Dr. Ross read notes of a case of Tuberculous Salpingitis for which laparotomy was performed.—Dr. Snow read notes of a case of Basal Phthisical Cavity treated surgically.—The President initiated a debate on the subject, Should the Bournemouth Medical Society take any active part in the campaign against Tuberculosis, and, if so, in what way will it be best to move in the matter? He said he thought the local medical society should take an active interest in the matter and coöperate with the National Association for the Prevention of Consumption, &c. He did not think the matter should be left solely to private enterprise to establish sanatoria for the so-called open-air treatment of tuberculosis.—The President and Dr. Arthur Ransome having given some particulars of the National Association for the Prevention of Consumption it was unanimously resolved:—

> That the Bournemouth Medical Society approve the necessity of forming a local branch of the National Association for the Prevention of Consumption and other forms of Tuberculosis and that seven members be appointed to act with an equal number of the Town Council, thus forming a provisional committee to further consider the matter.

At a meeting of the Town Council held on Jan. 19th they appointed the following seven members—viz., the Mayor, Alderman Hirons, Alderman Hosker, Councillor Roker, Councillor Jolliffe, Councillor Mate, and Councillor Kinsey-Morgan—to serve on the provisional committee proposed by the Bournemouth Medical Society to consider the desirability of forming a local branch of the National Association for the Prevention of Consumption and other forms of Tuberculosis.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on Jan. 20th, the Vice-President, Dr. R. Ostlere, being in the chair.—Mr. W. Campbell M'Donnell showed a case of Primary Optic Atrophy in a man, aged twenty-five years, without any nervous symptoms or previous causal taint.—Mr. Macdonald Brown showed a case of General Discrete Molluscum Fibrosum in a man, aged fifty-four years, who had been so affected for thirty-four years.—Dr. C. G. Mack read notes of a case of Large White Kidney in a woman, aged forty-nine years, whose symptoms were occipital headache and vomiting primarily. Fifteen days later death succeeded coma. The brain and membranes were found to be normal and the kidneys were large with adherent capsules and pale.—For the President was shown a case of Psoriasis of all the Nails of two years' standing in a man, aged sixty-one years.—Mr. W. Campbell M'Donnell read notes of a case of Parotitis, Tonsillitis, and Diphtheria in a girl, aged eight years, who had ailed several days and complained then of sore-throat and languor. On the tonsils were small white patches, the ordinary appearance of follicular tonsillitis. The temperature was 102° F. in the morning. A few days later both the submaxillary salivary glands were inflamed. In two more days the teeth could be scarcely parted and the left parotid salivary gland was inflamed. She progressed favourably until on the eleventh day of attendance fluid taken returned *viâ* the nose. Next day she could open the mouth; it was then found that there were two diphtheric patches at the base of the uvula and the palatal palsy had increased. Antitoxin was then injected and also on the next day but she died during an attack of dyspnœa.

HEALTH OF CARDIFF.—At the meeting of the Cardiff Health Committee held on Jan. 10th the medical officer of health, Dr. Walford, reported that 5520 births had been registered during 1898, giving a rate of 31 per 1000. The deaths numbered 2627, equal to a rate of 14·8 per 1000. This is the lowest death-rate since 1845 when returns were first taken. The rate of mortality from zymotic diseases was 2·52 per 1000.

A HOME FOR INEBRIATES.—At the meeting of the Gloucestershire County Council held on Jan. 9th it was reported that the committee of the Royal Victoria Home, Horfield, are erecting a public institution under the provisions of the Inebriates Act at Westbury-on-Trym and th they had applied to the council for a contribution. It w stated that the building will accommodate 880 patients a that it stands on 80 acres of land, the cost of the undertaki being estimated at £20,000. After some discussion council resolved to contribute £1000 towards the institu conditionally that the county should be entitled to 7 for twenty-five years at a cost of 6*d.* each per day. chairman (Sir J. E. Dorington, M.P.) added th committee of the Royal Victoria Home were in nego with other counties and probably it would becom reformatory for the southern part of England.

Reviews and Notices of Books.

Twentieth Century Practice of Medicine. Edited by THOMAS L. STEDMAN, M.D. New York. Vol. XV.: Infectious Diseases. London: Sampson Low, Marston and Co. 1898. Pp. 658.

THE general character of this valuable series of volumes needs no further comment in our columns, reviews of the preceding numbers having already appeared, so that we can at once turn to the consideration of the various contributions in the one now under consideration.

The first is on Influenza, by Dr. Ditmar Finkler. We have already referred to it in a leading article in our issue of Jan. 14th, p. 103, and we there designated it as one of the best monographs of the subject which we had met with. A full and most instructive *résumé* of the epidemiology of the disease is given, containing brief accounts of all the epidemics of influenza of which medical history affords evidence. The first records referring to pestilential diseases which are regarded by historians as descriptive of influenza are met with in Livy and refer to a pestilence in the year 412 B.C. According to August Hirsch the first influenza epidemic occurred in 1173 and he places it in his work as the first out of eighty. The pandemic of 1889-90, however, forms the starting-point of the modern history of the disease, and a full account of it is given. The various theories of the etiology are carefully analysed, but the view is maintained that it can only be spread by human intercourse and that atmospheric and other conditions play only inferior parts. Dr. Finkler agrees with Dr. Leichtenstern that "occupation and social position only in so far exert an influence on the frequency of the disease as certain occupations and positions in life lead to more or less contact with travellers" The micro-organism discovered by Dr. Pfeiffer in the year 1892 is considered by Dr. Finkler to be the pathogenic organism of the disease, and an exhaustive account is given of the characteristics, mode of culture, &c., of the bacillus. Dr. Pfeiffer's conclusions are also adopted, as follows: (1) any development of the influenza bacillus outside the human body, in the ground or in water, is impossible; (2) the spread of influenza by dried and powdered sputum can occur only to a very limited extent; and (3) the contagion, as a rule, is conveyed by the recent still moist secretion from the nasal and bronchial mucous membrane of influenza patients." The bacteriological examination of the sputum is laid considerable stress upon as the author believes that the bacillus can be demonstrated without difficulty, and he insists that in doubtful cases a positive diagnosis should not be made unless the organism has been found. Under the head of Pathology especial reference is made to the changes found in the respiratory tract

also reviews the evidence which has been advanced in favour of, and against, the doctrine of the autochthonous origin of this disease but is unable to arrive at any definite conclusion. He says: "My own opinion is that we have no right to sacrifice observed and attested facts to the lack of a satisfactory explanation of their causes and that we ought to cherish the hope that our science as it progresses will give us the key to discover the primary cause of typhus fever and we must content ourselves in the meanwhile with noting the facts and studying the secondary causes."

The descriptions of the symptoms of typhus fever are well and clearly defined and the section on diagnosis could only have been written by one who had had an extensive practical knowledge of the disease. An account of the experiments which have been tried to obtain an antitoxin is given but up to the time of writing no satisfactory results had been obtained.

The third contribution is on Plague, by Dr. Kitasato and Dr. Nakagawa. As would be expected, the section on the bacteriology of the disease forms most interesting reading. After detailing his own experiments Dr. Kitasato refers to those of Professor Yersin and says: "It has been quite generally assumed that the bacillus above described [the one discovered by the author] is identical with that of Yersin, but this assumption is incorrect"; and a summary is then given of their differences, and the writer then concludes: "Further bacteriological investigations of the plague are desirable and it is necessary that the scientific world should come to some definite conclusion as to the etiological bacilli before orrhotherapy and preventive inoculation can be instituted on a truly rational basis." The description of the disease does not follow the clinical arrangement usually adopted. Three types are taken: (1) glandular or bubonic plague; (2) pestis siderans or plague septicæmia; and (3) plague pneumonia. We do not consider this classification as comprehensive as the one adopted by the Bombay Plague Committee. This article has scarcely been brought up to date, only a very few lines being devoted to Professor Haffkine's investigations whilst Dr. Hankin's name does not appear.

The subject of Glanders is considered by Dr. Frank S. Billings. His definition is cumbersome and might almost be termed "ultra-scientific": "Glanders is an endogenous, obligatory-parasitic, invasio-infectious disease, due to the pathogenic action of a specific bacillus within the body of a suitable host which finds its historico-primary origin and its present genesis invariably among the solipeds, principally the horse, from which it is extended to other animals and to man, directly or indirectly, but not to cattle or swine." Medical terms are sufficiently numerous and expressive not to need others to be coined on the slightest provocation; and why (as is done in other parts of the contribution) are such Latin phrases employed as "causa interna," "causa externa" instead of the corresponding English phrases? Apart from this unnecessary use of Latin terms Dr. Billings has given us a very good account of the subject on which he writes, the section on Pathological Anatomy being especially interesting.

The same author contributes a paper on Anthrax which he describes as "an acute, exogenous, facultative, parasitic, infectious disease which is never general in its extension but invariably finds its locus of primary origin in telluric and caloric conditions of certain localities which supply the pathological necessities of its specific cause—bacillus anthracis." In describing the pathogenic organism the opportunity is taken of a disquisition on micro-organisms in general and very instructive reading it is. Anthrax being one of the bacilli the mode of growth, action, &c., of which is thoroughly understood such a digression is not out of place.

Dr. Billings's method of writing is peculiar, quotations from Scripture and Latin phrases being freely mixed with rather flowery English, but the knowledge that can be obtained by perusing the pages of his writings is none the less considerable.

A short article on Foot-and-Mouth Disease appears by Dr. Ismar Boas of Berlin.

Dr. Ponfick writes on Actinomycosis. Considering that Dr. Ponfick was one of the earliest observers of this complaint we are rather disappointed with his present contribution. It is very brief and the most modern literature does not seem to have been consulted. We notice especially that there is no reference to the work which has been done on the subject by English observers.

Dr. Keirle has evidently taken a good deal of trouble in putting together his paper on Rabies. The results of numerous experiments on animals are detailed and throw much light on the etiology of the disease, and also an account is given of the cases of eight boys who were bitten by a large dog in Baltimore in 1896; four of them died. The Pasteur method of treatment was adopted, but it was shown that the virus was from the dog and not from the treatment. We consider Dr. Keirle's contribution one of the best in this volume.

The last paper is on Pyæmia and Septicæmia and is written by Dr. J. M. Garton and Dr. J. M. Garton, jun. The sections on Prophylaxis and Treatment are particularly worthy of notice.

Vaccination: its Natural History and Pathology. By S. MONCKTON COPEMAN, M.A., M.D. Cantab., M.R.C.P. Lond. London: Macmillan and Co. 1899. Price 6s. net.

THIS volume, which consists of the Milroy Lectures delivered before the Royal College of Physicians in 1898, is published in the same convenient form as were Sir Richard Thorne's Milroy Lectures for 1891 on Diphtheria. Although we reproduced Dr. Copeman's lectures in full in THE LANCET for May 7th, 14th, and 21st, 1898, we may, in view of the fact that an increasing amount of interest is now being manifested in the natural history of vaccinia and variola, indicate for the benefit of our readers the contents of the present volume.

The introduction, which covers some forty pages, furnishes a somewhat impressionist but very readable sketch of the history of variola, of the introduction and practice of inoculation, and of Jenner's early work as regards cow-pox and horse-pox. Following this comes a chapter dealing with the relationship of variola and vaccinia, in which the author views the identity of small-pox and vaccinia as a subject still awaiting a definite solution. He prefers to speak of vaccinia as "one with small-pox," regarding it as a matter of relative indifference whether small-pox in its passage through the calf assumes as it were a new specificity, or becomes merely a modification of itself. In this chapter a very concise summary is given of the work done in the variolation of bovine animals. The history of the various lymph stocks, occupying as it does but six pages, is not dealt with quite so fully as, having regard to the controversies which have raged around this subject, we could have wished; but clearly Dr. Copeman's space has been limited and he has managed in it to convey a capital idea of very much of the subject of which he treats. The chapter relating to the bacteriology of vaccine lymph furnishes an historical account of the gradual progress which has been made towards the light in this direction, and the records of the author's experiments with regard to the susceptibility of monkeys to both vaccinia and variola which are set forth in the next chapter are highly interesting. As he remarks, the fact that these animals evince a marked receptivity to both vaccinia and variola goes far to dispose of the objection raised by Dr. Collins and Mr. Picton that the "variolous test" can no longer be applied to test the protective power of vaccine lymph. Of glycerinated calf lymph we have heard much of late and we may expect also to hear something of it in the future. Those, therefore, who wish to understand exactly what it is which is claimed for this lymph will do well to read Chapter IX. of Dr. Copeman's lectures. Certainly much of the correspondence which has recently taken place upon this subject has rendered it apparent that Dr. Copeman's claims in this direction have not been generally comprehended. Glycerine has doubtless been at times added to lymph as a *diluent* for very many years, but it was Dr. Copeman who undoubtedly ascertained by virtue of his experiments the germicidal properties of glycerine when added in certain definite proportions to vaccine lymph. It is the application of this discovery which it is to be hoped, will by its direct influence tend to diminish the allegations brought by ignorant persons against vaccination, and which will indirectly, by doing away with the necessity for puncturing the vaccine vesicles, reduce somewhat the after-complications which are, unfortunately, apt to occur from time to time. In connexion with this subject of glycerinated lymph several illustrations are furnished in the volume before us, showing by means of agar plates the gradual diminution of colonies in lymph treated with pure glycerine. With regard to the duration of activity of glycerinated calf lymph the author states that this is probably governed by several circumstances, and notably the condition of the calf itself. As to the question of potency, however, but little concern, according to Dr. Copeman, need be felt, and he tells us that from an average calf lymph can be furnished which, treated with glycerine, will suffice to vaccinate at least 5000 persons. This lymph will, we are glad to hear, retain its full activity for eight months. In an appendix to Dr. Copeman's instructive lectures is the very interesting report submitted by Sir Richard Thorne and himself to the Local Government Board on their joint inspection of the vaccination arrangements adopted in certain European countries.

The Surgical Anatomy of the Lymphatic Glands. By CECIL H. LEAF, M.A., M.B. Cantab., F.R.C.S. Eng., Demonstrator of Anatomy at the London Hospital. London: Archibald Constable and Co. 1898. 8vo. Pp. 72. Price 10s. 6d. net.

THE average student when dissecting ignores utterly all lymphatic glands and lymphatics; he looks upon them only as so much material which has to be cleared away in order to expose the structures which he considers of more importance. The examining bodies also have favoured this idea by refraining from asking questions on the positions of lymphatic glands and vessels; but when the student commences the study of medicine and surgery he finds that the lymphatic system has an importance with which he had never previously associated it. The aim of this book is to give by means of a series of well-executed diagrams the positions of the chief groups of lymphatic glands. For the last three years Mr. Leaf has been making a large number of researches as to the situation of these glands and he has received much assistance in these investigations from the use of formalin. A large quantity of a dilute solution of this liquid was injected into the internal jugular vein and common carotid artery of a subject for one month and when the body was dissected later it was found that the glands were well hardened and that the lymphatic vessels could be seen as semi-transparent whitish cords which were so tough that when the glands were pulled from their bed the vessels were partly drawn out also. The author has not attempted, except incidentally, to point out the areas which correspond to each group of glands, but we echo his hope that he will work out these points later.

With a few exceptions all the diagrams are original. We have already mentioned that they are well executed, but that is a feeble expression of the excellence with which these diagrams have been reproduced; nearly all the plates are coloured and they number eighteen. They are very good examples of chromo-lithography.

In a few cases Mr. Leaf has thought it advisable to rename certain groups of glands. It is, as a rule, a pity to introduce fresh names for it tends to confusion, but it is here probably justifiable.

It would serve no purpose to describe more fully the contents of this work, but there is one point which deserves particular notice. In some of the lower vertebrates several communications are known to exist between the lymphatics and the veins, but in man at only two points have lymphatics been found to pour their contents into the venous system. Mr. Leaf has discovered that in the inguinal region lymphatic vessels exist which divide—one branch going to a lymphatic gland and the other joining a vein. These observations are of great interest and the point deserves re-examination in order that they may be confirmed, but there is no *a priori* impossibility in the existence of such a communication The only real fault we can find in the book is that it possesses no index.

LIBRARY TABLE

Herbert Fry's Royal Guide to the London Charities for 1899. Edited by JOHN LANE. London: Chatto and Windus. Price 1*s.* 6*d.*—The large amount of benevolent work operating in the great city of London is usefully chronicled in a systematic manner by Mr. Lane. So far as we have been able to verify the references they are both accurate and up to date; but the compiler, we think, errs on the side of including rather more institutions under the head of "charities" than is quite consistent with the true interpretation of even this much-abused word For instance, we feel at a loss to quite comprehend in what way the London Anti-Vivisection Society, the National Anti-Vivisection Society, and certain religious or polemical institutions can legitimately be classed as "charities"; and the editor apparently shares our scepticism, seeing that the column opposite these societies, headed "Number of persons benefited last year," is left blank. It is worthy of note that the contributions to the various charitable funds promoted by the Lord Mayor at the Mansion House last year amounted to the large total of £700,000.

Messrs. John Wright and Co., Bristol, send us three little books in white paper covers lettered in gold, entitled, *Golden Rules of Surgical Practice*, *Golden Rules of Gynæcology*, and *Golden Rules of Obstetric Practice*. For works which if they are to be of any use should be constantly consulted we think the "get up" is a mistake, for it is modelled on the fashionable religious little books which were popular a few years ago under some such title as "Gold Dust." They are written respectively by Mr Harry Fenwick, Dr. S. J. Aarons, and Dr. W. E. Fothergill, and contain aphorisms and maxims of the greatest possible use not only to students and house surgeons but to practitioners of an older growth. They are the kind of points about which everyone when reminded of them says, "but I knew that," and they are also just those

in the November number of the *Journal of Experimental Medicine* is the extraordinary number and beauty of the photographs and coloured illustrations with which some of the articles are illustrated. We seldom see in any publication such a number of expensive illustrations brought together. Eight of the plates, containing 34 beautiful drawings, are coloured, the remainder, with the exception of one coloured drawing, are exquisitely reproduced photo-micrographs. If we may make one criticism it is that in one or two instances the articles are over-illustrated and that a smaller number of drawings would have been sufficient to demonstrate the various conditions dealt with in the text. The result of all this is that occasionally the article appears to assume an importance somewhat out of proportion to its real value. One of the most important of the articles is that dealing with a Form of Degeneration of Striated Muscle met with in the Uvula, by A G. Hoen, a paper of great interest from the fact that so little has hitherto been done on this subject. The author finds that in the relaxed uvula of inveterate smokers and those suffering from chronic pharyngitis there are degenerated muscular fibres in which proliferation of "interstitial" nuclei, granular disintegration of some of the individual fibrillæ, pigmentation of the nuclei of the muscles, and the formation of swollen and œdematous-looking patches occur. Dr. Ludwig Hektoen returns to the question of multi-nucleated giant cells and gives a record of his studies on these structures in coagulated blood-serum as it is being absorbed in the anterior chamber of the rabbit's eye. He still maintains that these giant cells may subdivide into uninuclear small cells and holds that they bear out his contention "that the giant cells in healing non-degenerated tubercular tissue may separate into small living cells and that the giant cells of tuberculosis are not necrobiotic elements from the very moment and from the very mode of their formation, as has been the general teaching, especially in Germany." Dr. W. L. Worcester contributes a paper on Regeneration of Nerve Fibres in the Central Nervous System; and Dr. F. B. Mallory gives a most careful Histological Study of Typhoid Fever. As a result of his investigations Dr. Mallory comes to the following conclusions: that the typhoid bacillus produces a mild diffusible toxin, partly within the intestinal tract and partly within the blood and organs of the body; that it produces proliferation of endothelial cells which acquire what he calls "malignant properties"; that the cells have eccentric nuclei and that they are markedly phagocytic; that they occur where the circulation is slowest, but that they may be found in every part of the lymphatic system of the body which the toxin may reach; that these cells pass through the liver and lungs and get into the general circulation, some also coming from the abdominal lymphatics through the thoracic duct; and they may give rise to vascular emboli. Dr. Mallory maintains that histologically the typhoid process is proliferative and stands in close relationship to tuberculosis; the lesions, however, are diffuse and bear no intimate relation to the typhoid bacillus, whilst the tuberculous process is focal and stands in closest relation to the tubercle bacillus. The other

Production of Acid by Allied Bacteria, by Charles H. Higgins, B.S., D.V.S.; and Diffuse Sarcoma of the Cerebral and Spinal Pia Mater, by George H. Weaver, M.D.

The Journal of State Medicine. Vol. VII. No. 1. London: Baillière, Tindall, and Cox. Price 2s.—The January number of this journal is largely devoted to the subject of Tuberculosis, containing as it does Sir Richard Thorne's second Harben Lecture which deals mainly with the influence of milk in the spread of this disease, and Mr. Christopher Middleton's paper on Compensation for Tuberculosis which was read at the veterinary conference of the Dublin Congress of the Royal Institute of Public Health. There is, too, a paper by Mr. Thomas McGuinness, M.R.C.V.S., on the Housing of Cattle in its Bearing on the Elimination of Tuberculosis, and one on the Milk of Tuberculous Animals by Mr. F. C. Mason, M.R.C.V.S. *As a fitting accompaniment to these* papers this volume contains a good portrait of Mr. Chaplin, the President of the Local Government Board, who may soon have to deal in a legislative sense with this important subject.

West London Medical Journal.—One of the original communications in the January number is a paper by Dr. F. J. McCann on Difficulties in the Diagnosis of Early Tubal Pregnancy. He describes two successful operations for this condition and to show how many signs and symptoms of tubal pregnancy may be found apart from it he gives some details of a case of dermoid cyst of the ovary. Dr. A. W. Addinsell describes a case of Ovariotomy followed by Parotitis; some time before the operation the patient suffered severely from a strong solution of perchloride of mercury having been given as an enema in mistake for soap and water.

Birmingham Medical Review.—Dr. C. E. Purslow, writing in the January number on the Treatment of Uterine Inertia, mentions that he has found quinine taken in 5-grain doses at intervals of two hours to be a valuable oxytocic, and that in several cases where the first stage of labour was prolonged for five days and upwards bipolar podalic version, with careful gradual extraction, was followed by firm contraction of the uterus without the least tendency to post-partum hæmorrhage, thus contrasting favourably with the ordinary experience of forceps under similar conditions. M. S. V. Wechsler contributes an illustrated article in the French language on an Abscess of the Parietal Lobe of the Right Cerebral Hemisphere. Mr. Christopher Martin writes on the Treatment of Puerperal Fever.

Dublin Journal of Medical Science.—The original communications in the January number are by Dr. J. M. Finny on Acute Hæmorrhagic Ascites, by Mr. J. S. McArdle on the Operative Treatment of Hernia, by Dr. H. S. Purdon on Lupus Erythematosus, and by Dr. Patrick Letters on Public Health and Preventable Disease in the Counties of Cork, Kerry, and Waterford.

La Grèce Médicale.—This monthly journal, printed entirely in the French language, made its first appearance at Syra in Greece in December, 1898. Dr. John Foustanos of Syra, who has for several years conducted the journal *'Ιατρικὴ Πρόοδος* (Le Progrès Médical), printed entirely in Greek, believes that the unfamiliarity of most European nations with modern Greek has prevented foreigners from realising what progress has of late been made by his countrymen in medical science and literature, and with the view of remedying this deficiency he has brought out *La Grèce Médicale*, which is distinct from and very much smaller than *'Ιατρικὴ Πρόοδος*, although it is intended that a portion of the contents, such as reviews of books, shall appear in French in the *one* journal and in Greek in the other. Among the original communications in the first two numbers of *La Grèce Médicale* may be mentioned papers on the Malarial Diathesis in the Caucasus by Dr. Timoleon Triantaphyllides of Batoum; on the Use of Berberine (the alkaloid of Berberis vulgaris) in the Treatment of Malarial Enlargement of the Spleen by Dr. G. T. Lascarato of Patras; and on Large Uric Acid Calculi in the Urethra by the editor. The subscription to the journal is 4 francs per annum.

Analytical Records

FROM

THE LANCET LABORATORY.

(1) THIOCOL; AND (2) AIROL (ROCHE).

(HUGO LORENZ, 7 AND 8, IDOL-LANE, E.C.)

THIOCOL is a comparatively new guaiacol derivative which, unlike most guaiacol compounds, is easily soluble in water. It is a white crystalline powder smelling freely of guaiacol. As a matter of fact it is the guaiacol-sulphonate of potassium. It is said to contain 60 per cent. of guaiacol. The advantages which this compound possesses over guaiacol are that while its administration is said to give encouraging results in the treatment of pulmonary tuberculosis it does not irritate the mucous membrane, while being freely soluble in water it is more readily assimilable. Airol is the oxyiodogallate of bismuth. It yields abundance of iodine on treatment with nitric acid. In spite of this it is devoid of iodous smell. It is suggested as an advantageous substitute for iodoform possessing three times the bulk of pure iodoform. These properties combine to make airol an excellent antiseptic application, especially in the form of a dusting powder, or it may be used with an unguent.

LEUBE ROSENTHAL'S MEAT SOLUTION.

(H. POTHS AND CO., 4, 5, AND 6, BURY-COURT, ST. MARY AXE, E.C.)

The analysis of this preparation gave the following results: moisture, 65·22 per cent.; meat substances insoluble in cold water, 14·64 per cent.; meat substances soluble in cold water, 11·64 per cent.; and fat, 4·54 per cent. It is not quite clear to us why this preparation is called a "solution." It presents the appearance of pulped beef, that is, beef in a fine state of division. It possesses an excellent flavour and makes a very palatable broth or soup. Doubtless on account of the fine pulpy state to which the muscular fibre has been reduced it is easily digestible. As regards nutrient value it is decidedly superior to a clear extract which invariably contains a very large amount of stimulating extractive principles in proportion to real nutritives. It contains only traces of proteoses.

OLD IRISH WHISKY.

(JOHN McLAUGHLIN, COLERAINE.)

It is conceivable through the enormous demand during recent years for Scotch whisky to the exclusion of Irish whisky that the stock of the latter has been laid by with the advantage that it has since undergone maturation in cask under the influence of age. For this reason the chances of genuine Irish whisky being old are considerable. We have recently examined a specimen sent to us by the above firm of distillers and the results of examination and analysis are quite in accordance with the statement that it was distilled as long ago as 1889. The analytical results were as follows: alcohol, by weight 43·00 per cent., by volume 50·57 per cent., equal to proof spirit 88·62 per cent.; *extractives*, 0·17 per cent.; mineral matter, 0·05 per cent.; and acidity reckoned as acetic acid, 0·06 per cent.

The spirit is decidedly dark in colour and the taste characteristic of good Irish whisky—i.e., peaty but very smooth and mellow. It is destitute of that harsh character which makes raw and young spirit dietetically unsuitable.

ITALIAN WINES.

(EGIDIO VITALI, 5 AND 6, GREAT WINCHESTER STREET, E.C.)

The specimens received, all of which we have submitted to analysis and examination, represent most of the types of wine which are imported into this country from Italy. We will record first the figures of analyses. Capri (white wine): extractives, 1·55 per cent.; mineral matter, 0·25 per cent.; sugar, 0·76 per cent.; tartaric acid, 0·52 per cent.; acetic acid, 0·31 per cent.; alcohol, by weight 11·62 per cent., by volume 14·37 per cent., equal to proof spirit 25·18 per cent. Falerno (white wine): extractives, 1·12 per cent.; mineral matter, 0·19 per cent.; sugar, 0·11 per cent.; tartaric acid, 0·66 per cent.; acetic acid, 0·13 per cent.; alcohol, by weight 8·64 per cent., by volume 10·73 per cent., equal to proof spirit 18·81 per cent. Chianti (red wine): extractives, 2·00 per cent.; mineral matter, 0·29 per cent.; sugar, 0·17 per cent.; tartaric acid, 0·60 per cent.; acetic acid, 0·18 per cent.; *alcohol*, by weight 9·38 per cent., by volume 11·61 per cent., equal to proof spirit 20·35 per cent. Barolo (red wine): extractives, 2·07 per cent.; mineral matter, 0·24 per cent.; sugar, 0·18 per cent.; tartaric acid, 0·45 per cent.; acetic acid, 0·25 per cent.; alcohol, by weight 10·85 per cent., by volume 13·43 per cent., equal to proof spirit 23·54 per cent. Barolo Tenimento (red wine): extractives, 1·88 per cent.; *mineral matter*, 0·22 per cent.; sugar, 0·13 per cent.; tartaric acid, 0·48 per cent.; acetic acid, 0·24 per cent.; alcohol, by weight 10·85 per cent., by volume 13·43 per cent., equal to proof spirit 23·54 per cent. Valtellina (red wine): extractives, 1·99 per cent.; mineral matter, 0·27 per cent.; sugar, 0·13 per cent.; tartaric acid, 0·41 per cent.; acetic acid, 0·29 per cent.; alcohol, by weight 9·36 per cent., by volume 11·61 per cent., equal to proof spirit 20·35 per cent. Egidio Vitali (sparkling white wine): extractives, 5·99 per cent.; *mineral matter*, 0·20 per cent.; sugar, 3·67 per cent.; tartaric acid, 0·79 per cent.; *acetic acid*, 0·26 per cent.; alcohol, by weight 10·08 per cent., by volume 12·49 per cent., equal to proof spirit 21·89 per cent. Space will only admit of brief comment on these results. The noteworthy features of the white wines are a very small percentage of saccharine constituents, a very light alcoholic strength, and a small percentage of extractive matters. Falerno is a high-class wine of very agreeable character and remarkably light with a very small percentage of sugar. Capri is similar but distinctly sweeter though the sugar amounts to no more than ¾ per cent. Both wines have the excellent delicate flavour and bouquet of the grape. In considering the white wines we may include the sparkling Egidio Vitali which is hardly distinguishable from good champagne. It is fairly dry and of a tone and quality characteristic of champagne. It is very moderate in price and a genuine product of the grape. As will be seen from the analysis the red wines also show results in accordance with genuineness. The Chianti is a dry, *faintly astringent* claret *of good fruity character*. Valtellina is full-bodied and satisfactory to the palate. Barolo, again, is of the Burgundy type, a rich wine full of vinous character and yet of light alcoholic strength. Lastly, we have examined a liqueur called "Eucalyptine" made by the Trappiste Fathers at the Three Fountains, St. Paolo, at Rome. It is a very agreeable liqueur containing the volatile and aromatic constituents of the eucalyptus plant. It is probably digestive and is regarded, though with little foundation we think, as a specific in malaria. These wines are excellent in class and character and undoubtedly pure and genuine products of the grape. Many of them though full-bodied and fruity to the taste are remarkably light in regard to alcoholic strength. They therefore afford a light and agreeable form of stimulant for dietetic purposes.

VARNISHED COATED PILLS.

(MR. S. WAND, HAYMARKET, LEICESTER.)

The special point about some pills which we have received for examination from the above firm is the coating. The pills are highly finished in appearance with a lustrous coating of a varnish-like substance. The pills examined contained sulphate of iron and carbonate of potassium in accordance with Blaud's formula. On placing them in a solution of an acid strength equal to the gastric juice we found that the coating in a few minutes became detached in flakes, the contents thus being soon exposed to the solvent and disintegrating *action of the fluid*. *The unstable iron salt* was found intact, for on examining the solution the iron proved to be entirely in the unoxidised condition. Despite therefore the protective action of the coating against the changes induced by contact with air it yields readily to the action of acid solutions of the nature of gastric juice.

MARSALA WINES.

(INGHAM WHITAKER AND CO. MARSALA AGENCY: STUART N. CORLETT, 11, TRINITY-SQUARE, TOWER-HILL, E.C.)

Two types of Marsala wine have been submitted to us analogous to the "fino" and "oloroso" classes respectively of sherry. The results of analysis were as follows:—Racalia: extractives, 3·68 per cent.; mineral matter, 0·48 per cent.; tartaric acid, 0·67 per cent.; acetic acid, 0·15 per cent.; sugar, 0·73 per cent.; alcohol, by weight 12·69 per cent., by volume 15·68 per cent., equal to proof spirit 27·48 per cent. It is a dry, light, and pleasant wine. Amoroso: extractives, 7·07 per cent.; mineral matter, 0·63 per cent.; tartaric acid, 0·68 per cent.; acetic acid, 0·13 per cent., sugar, 4·8 per cent., alcohol, by weight 16·69 per cent., by volume 20·52 per cent., equal to proof spirit 35·95 *per cent*. As will be seen this wine is more full-bodied than the previous specimen. It is a generous pure wine suitable *for after dinner use*, while Racalia may be considered on account of its relatively light alcoholic strength better adapted for table purposes. Both wines contain an important amount of sulphate of potassium, from which we infer that the grapes have been treated, as in the preparation of sherry, with sulphate of lime. As was pointed out in the report of THE LANCET Analytical Commission on Sherry in THE LANCET of Oct. 29th, 1898, this treatment favours the production of vinous ethers, while no objection can *be reasonably* raised against the method so long as it is kept within certain limits.

FIRST REPORT OF THE ROYAL COMMISSIONERS ON THE METROPOLITAN WATER-SUPPLY.

THE first report of *Her Majesty's Commissioners* appointed to inquire into the subject of the water-supply within the limits of the metropolitan water companies was issued by Her Majesty's Stationery Office last week. It is dated Dec. 20th, 1898. The report deals only with one section of the reference—namely, "whether it is practicable to connect any two or more different systems of supply now administered by the eight metropolitan companies; and, if so, by whom, and in what proportion, should the cost of connecting them be borne, and what are the legal powers necessary to give effect to any such arrangement." The report is divided into eight sections, all of which are important. The chief recommendations of the Commissioners may be given in their own words as expressed in Section 5, namely, that "from the point of view of the consumer ...... inter-communication between the several systems of supply, provided it is carried out to a reasonable extent and on well-considered lines, is not only useful and expedient but necessary." The report is signed by the Chairman and by all the other Commissioners.

The first section of the report gives an account of proposals of the associated metropolitan water companies which were made to the Commissioners at the outset of their inquiry. The companies announced that they had come to the conclusion that inter-communication would be a convenience and stated that they were prepared to promote a Bill in Parliament during the next session which would make it unnecessary for the Commissioners to inquire into the details of any particular scheme and would obviate difficulties due to the existing statutory obligations of the companies and restrictions which are at present placed upon them in regard to the application of their powers to purposes other than those required for their own districts. The counsel for the companies communicated a series of resolutions which had been passed by the directors of the associated companies and which stated their views as to the form which legislation should assume in dealing with the question. These resolutions were as follows:—

1. The companies forthwith to consider what works are required for the above objects and to submit proposals to the Local Government Board for approval. The Local Government Board to be empowered to approve and authorise such works with or without modifications or to authorise and order other works for the like objects. 2. Further works for the above objects may in like manner be from time to time authorised and ordered if and when required. 3. The respective companies to carry out in their respective districts all works so authorised. 4. The Local Government Board to be empowered to authorise the supply of surplus water from the works of any company, to the works of any other company for the time being requiring the same, and the Local Government Board to have power in case of emergency to authorise any of the companies to take more water from the Thames than they are now authorised to take. 5. All expenditure of the respective companies in relation to any such works to be deemed capital expenditure, and for the purpose of meeting such expenditure the Local Government Board to be empowered from time to time to authorise the respective companies to issue an additional amount of debenture stock. 6. No contribution to any sinking fund to be made in respect of capital issued for the foregoing objects. 7. Subject to reasonable contribution by any company taking and utilising by means of the proposed works and powers water which it would not otherwise have been able to take and utilise, the interest on debenture stock applied by the respective companies for the foregoing works to be borne by the eight companies in proportion to their respective water rentals. 8. Any company taking water from another company to pay for such water to the company supplying it at a rate to be agreed upon or fixed by arbitration. 9. A standing arbitrator to be appointed by the eight companies, and failing such appointment by the Local Government Board, and in case the respective companies do not agree amongst themselves, such arbitrator at the end of each year to decide as to the contribution of any company taking and utilising the water rendered available by the posed works and also to decide any matters in difference between the mpanies.

The second section of the report deals with three schemes of intercommunication which were submitted. The first scheme was drawn up by the engineers of the eight metropolitan companies and was dated Oct. 18th, 1897. This scheme was afterwards withdrawn and an amended report of the engineers of the London water companies, dated Oct. 24th, 1898, was substituted for it. The amended report was prepared with special reference to the circumstances of the year and the scheme was made possible by the fact that works belonging to the Southwark and Vauxhall Company at Battersea might be temporarily utilised. The amended report is published as an appendix to the report of the Royal Commissioners. A full account of this scheme has recently appeared in THE LANCET,[1] and it is unnecessary to reproduce it. The third scheme submitted to the Commissioners is described by them as being in effect a portion of Scheme No. 2, and has already been partially carried out and put into operation to meet the emergencies of the East London Company during the past year.

The third section of the report deals with the present capacity of each company to contribute water to any other company which may be in need of it. The Commissioners state that in view of the fact that the utility of connexions between systems of supply must materially depend on the possession by several companies of surplus supplies of water they thought it necessary to examine the engineer of each company on this particular point. The information obtained was briefly as follows:—

The Chelsea Company possess a statutory right to abstract 22,000,000 gallons daily from the Thames. At the present time, however, the company are only able to filter, pump, and pass into their mains 17,000,000 gallons daily. The engineer gave it as his opinion that during the months of June, July, August, and September the company could not spare more than 2,000,000 or 3,000,000 gallons daily. The Commissioners therefore infer that in order to utilise for transfer to any other company the balance of the amount of water which the company has power to abstract from the Thames it would be necessary to provide additional filters, pumping-power, and mains.

In the case of the Grand Junction Company only 1,500,000 gallons daily can be spared. The company has a statutory right to take 24,500,000 gallons. During the summer of 1898 the maximum daily amount taken was 23,500,000 gallons and the average daily abstraction from January to October was 21,000,000 gallons. Additional pumping power and new mains would be required in order to enable the company to contribute to others any considerable amount of water.

The condition of the Kent Company is unique. The wells from which the water is derived are scattered throughout a large district and the water is obtained from the store contained in the chalk formation. As there are a large number of wells the company has not found it needful to provide large mains for the carriage of water as companies which obtain their water wholly or in part from one intake must necessarily do. There is no cause to apprehend sudden or extensive curtailment of water-supply from drought as the reservoir in the chalk tapped by the wells is so large that it is very slowly affected by deficiencies in the rainfall. It follows that the Kent company have no reason to have a large reserve supply either with regard to pumping-power or to storage reservoirs. Hence the company would not be able to transfer much water and there is no probability that a large amount would be wanted by them from other companies. At the present time the company can obtain 25,000,000 gallons daily. The largest amount supplied in 1898 in any one day was 21,000,000 gallons. At the present time the company can supply 2,000,000 gallons to a district outside its own area. For a short time during the year 1898 the company was brought to the limit of its supply in consequence of a breakdown of the pumping engine at Wilmington well and a coincident failure in the well at Orpington. Works are, however, nearly completed which will increase the available water-supply of the company.

The Lambeth Company could at present spare no water. The company have statutory power to abstract from the Thames 24,500,000 gallons each twenty-four hours. The average daily supply of the company in the year 1897 was 23,688,305 gallons, and the rate of supply in September, 1898, was 31,891,317 gallons. The company contend that the statutory limit of abstraction of water from the Thames is not exceeded, and that the surplus water is obtained from the gravel beds adjoining the river, but the Commissioners point out that according to the report of Lord Balfour's Commission abstraction from the gravel is equivalent to abstraction from the river itself.

The West Middlesex Company has a right to abstract 24,500,000 gallons from the Thames in each twenty-four hours. The available surplus for the five months from June to October, 1898, was 1,542,106 gallons. The daily supply of water to customers is increasing yearly at the rate of about 300,000 gallons and the limit of the amount of water which the company could therefore spare is 1,500,000 gallons daily. In order to increase the capacity of the company to supply water it would be necessary to have further statutory powers for taking water; a main would have to be laid from Hampton to Barnes and probably additional pumping power would have to be erected and in the case of any quantity exceeding 5,000,000 gallons a day an additional main would have to be laid from Barnes to Campden Hill.

(To be continued.)

BOARDS OF GUARDIANS AND THE VACCINATION ACT.—The Tiverton Board of Guardians on Jan. 10th decided to petition Parliament to repeal or amend the Vaccination Act of 1898, pointing out that in their union no difficulty had been experienced in enforcing vaccination prior to that Act.—At a meeting of the Okehampton Board of Guardians held on Jan. 8th it was decided to send a petition against the new Vaccination Act to the Local Government Board, both Houses of Parliament, and the Devon County Council.—The Merthyr Tydvil Board of Guardians on Jan. 7th decided to petition against the Vaccination Act.

[1] THE LANCET, Jan. 7th, 1899, p. 49.

THE LANCET.

LONDON SATURDAY, JANUARY 28, 1899

WE have lately devoted much space to accounts of the Irish medical dispensary system and to speculations on the probable effects of recent legislation on this system and on sanitation in Ireland Our Special Commissioner's report will well repay the study of those who are apt to think that medical grievances have reached their acme in England They have the advantage of being written by one who is not personally interested in the system and who is very familiar with investigations into schemes for exploiting the medical profession in the supposed interest of the humbler sections of society without due reference to the claims of the medical man or to the needs of the sick

To-day we revert to the subject of the Irish dispensary system in connexion with a report on the matter by the Irish Medical Association—a document of extreme interest and of great moderation of statement which cannot fail to bring home to those who are responsible for medical attendance on the poor of Ireland the necessity for an immediate reform of the existing system alike in the interest of the poor and of the medical profession The peculiar economic conditions of Ireland, the area of the country and the large number of the inhabitants devoted to agricultural purposes render some such system—for the present at least—indispensable But it is scarcely credible that the grievances set forth by the Irish Medical Association should continue to exist and their adequate redress should be one of the first fruits of an improved and more liberal measure of local government for Ireland The case for such improvement combines every element that can appeal to a people like the Irish The existing system does not meet the wants of the Irish poor for whom it was originally intended, and the plight of the dispensary medical officer working on sometimes for fifty years till seventy, eighty, or ninety years of age without promotion and without any certainty of pension or superannuation, is pitiable beyond description and thoroughly discreditable to the State We give elsewhere a short abstract of the Report of the Irish Medical Association on the grievances of the service They are discussed under various heads: the abuse of tickets, the small remuneration with no allowance for travelling expenses, the absence of any provision for a break in the monotony of work in the shape of an annual vacation, the absence of provision for superannuation or for earlier retirement under exceptional circumstances, and the absence of all prizes and promotion in the service Tickets are abused by being issued to persons of property and position without system, without inquiry into the gravity of cases, at all hours of the day, and the hapless dispensary medical officer has often to retrace his ground for miles, perhaps over bogs or mountains—all this for an average salary of £108, as he ministers to an average population of 6557 over an average area of 44½ square miles The salary itself scarcely suffices for the necessaries of life and yet all the expenses of travelling in these sparse and remote regions have to be paid out of it Vaccination is, it is true, an extra But it is not remunerative Stations are so distant that often the fees do little more than pay the car hire An instance in the report is given where the dispensary medical officer had to visit twice a quarter 7 stations, vaccinating 100 children a year For this he received the handsome sum of £10, out of which he had to pay £9 16s for his car Let us suppose that this duty was not performed and that the poor of Ireland were left to the tender mercies of small pox What would the misery of that alternative be, and what we may add, would be its cost in a country where crowded homes and "wakes" give such diseases full scope for development? The full hardship to the medical officer under the existing system is strikingly shown in the report under the head of Superannuation It is difficult to say which case is the more pitiable—that of the young medical officer dying—often from infectious disease—at an average age of thirty seven years, or that of the old one longing for the rest that is due to him but afraid to resign in the absence of a pension for work which he may have been at for half a century The report gives instances which will surprise those who read it and which seem to justify the remark of those responsible for it that the severity and danger of dispensary duty are so great that few dispensary medical officers reach a retiring age Our Special Commissioner has dealt powerfully with the right to pensions of men who in a sense more vivid than other Civil Servants devote their whole lives and their whole time to the case of the poor The cases in this report quoted from SIR WILLIAM THOMSON who has done so much to elucidate this subject strikingly enforce the arguments employed by our Commissioner and will we hope, attract attention in the proper quarter

The report concludes with recommendations for the remedy of the evils so well described One evil must be faced resolutely—that of issuing tickets to unfit persons and from unworthy motives But it is equally essential in the interest of the tone and character of the service that the rate of remuneration should be increased and that some elements of reward and promotion should be introduced into a career so monotonous so laborious and so responsible These needed reforms in one of the most important services affecting the welfare of the Irish people will not be accomplished without firmness and persistence and some show of independence on the part of the profession in Ireland The profession must be true to itself The Irish people enjoy the reputation of being chivalrous and generous to medical men We believe this to be their intention They cannot as regards the Poor law Department give adequate fees Much poverty in the past has made that impossible, but they have it now in their own power to deal with some approach to justice with the profession in its public relations and that they will do so we confidently anticipate, and we trust that they will in so doing be encouraged and assisted by the Local Government Board of Ireland.

A LOCAL GOVERNMENT BOARD inquiry of more than usual interest from a public health point of view was held at Havant on Dec. 13th and 23rd, 1898, before Dr. TIMBRELL BULSTRODE and Mr. TULLOCH, M.Inst.C.E. Havant is a small market town in Hampshire, about 8 miles from Portsmouth. At the last census its population was 3474, but since 1891 it has largely increased in size and at the present time it has a rateable value of £13,398. Almost in the centre of the town and about 60 or 70 yards south of the main street are several springs belonging to the Borough of Portsmouth Water Company which supplies Portsmouth (having a population of nearly 200,000), Havant itself, several surrounding villages, garrison forts, and the ships in Portsmouth Harbour. In 1897, owing to complaints from the War Office, Dr. THEODORE THOMSON of the Local Government Board, assisted by Mr. WHITAKER, F.R.S., made a careful examination of the company's springs and their surroundings, and in the report to the Board attention was drawn to the possible risk of pollution of the springs from the insanitary condition of Havant. A copy of this report was sent by the Local Government Board to the Portsmouth Corporation who in turn forwarded it to the water company asking what steps in view of that report were being taken for the protection of the water. The authorities of the company replied that everything in their power had already been done for the protection of the springs and that if any risk of pollution still existed it was due to the Havant urban and rural councils having neglected to perform the duties required of them by the Public Health Acts, and especially in having neglected to provide their districts with a sufficient system of sewerage; they, the water company, therefore requested the Portsmouth Corporation to support them in a petition to the Local Government Board complaining of the default made by the Havant urban and rural district councils, and asking the board to limit a time for the performance by these councils of their duties in respect to the sewerage of their districts. The result was the present inquiry.

It will be at once evident from the foregoing remarks as to Havant that apart altogether from the advantage to the people of Havant itself the maintenance as far as possible of a perfect system of sanitation should have been regarded by the district councils as the most important duty entrusted to their hands and that no effort should have been spared to avoid all risk of pollution to the springs which supplied *not only themselves* but between 200,000 and 300,000 persons in addition. Unfortunately, according to the evidence given by Professor CORFIELD, Mr. BALDWIN LATHAM, Mr. E. C. SMITH, and other experts, this is very far from being the case, and the existing state of affairs is in no sense creditable to those responsible for it. It appears from the evidence given that the only sewers in the district are confined almost exclusively to parts of the four main streets, and that they consist of nine- and six-inch pipes some of which are jointed with clay. These which are but a little distance below the surface of the road were laid over thirty years ago and were not intended to take solid matter; in fact, the houses connected with them are in certain instances provided with a catchment basin to intercept and prevent the solids from gaining access to the sewers; the majority of houses are provided with cesspits nearly all of which are pervious to water and as they are but rarely emptied it is evident that soakage is continuously taking place into the surrounding soil. Four or five streets in the neighbourhood of a couple of schools have no system of drainage or even sinks, the slop water being disposed of by being thrown into the road gutters; in one house the drain runs without any intercepting trap straight into an unventilated cesspool. It is unnecessary to enumerate all the flagrant insanitary conditions described at the inquiry; one more, and perhaps the most glaring, example was a stream which runs through the centre of Havant and which receives in its course the overflow from several cesspools, the manufacturing refuse of a parchment works and a chamois leather manufactory; it then skirts the enclosures of the water company, and, finally, after feeding a watercress bed, discharges into Langstone Harbour, in which, by the way, are a number of oyster beds. All these conditions and numerous others were practically admitted as existing by the Havant Urban Council, the only argument brought forward being that such had always been the *state of affairs* in the past.

It would probably be rather difficult to find a better example of the supineness of small urban and rural sanitary authorities than was exhibited in this town of Havant, a fairly accurate estimation of the value of sanitation in whose eyes may be adduced from an advertisement which appeared not long ago in the local papers for the appointment of a sanitary inspector whose salary was to be £30 a year, and even that munificent sum is £5 more than is paid to the Havant medical officer of health. The insanitary condition of small towns like Havant—and anyone conversant with rural sanitation could name numerous places equally bad—is a very difficult subject to deal with and if the indifference of such towns to sanitation recoiled only on their own heads it would not be such a serious matter; but when, as in this case, thousands of lives are jeopardised by ignorance then we are face to face with a danger which affects the country generally. Nor is it only in regard to the pollution of a water-supply that the danger to the general public occurs; quite as important is the danger to the milk-supply. The majority of the milk-supplies of the large towns are obtained from rural and small urban districts. The sanitary supervision of these districts is vested generally in the farmers and cow-owners in the district, and it is commonly found by rural medical officers of health that it is hopeless to try to get regulations enforced as to the air space in cowsheds, pure water-supply, and cleanliness, when the enforcement of such regulations will entail a certain amount of expenditure by these farmers and cow-keepers. It was hoped that the appointment of county medical officers of health would tend to improve the condition of these rural and small urban districts, and in many counties a marked improvement has taken place consequent upon such appointments. But several county councils, of which Hampshire is one, have not yet appointed a medical officer and thus the district councils are allowed to go on in their own ignorant ashion, meeting every suggestion for improvement with the argument that what was good enough for their fathers is good enough for them and there is no one to try to arouse them to a sense of duty or to point out that the preservation of health is the most important duty entrusted to their hands and should be maintained even at the addition of a penny or twopence in the £ to the rates. Ignorance and indifference are the worst enemies which modern sanitation has to deal with, and methods have yet to be devised to bring home to district councils in many parts of the country the advantages direct and indirect which result from obedience to the laws of health. It is, however, certainly to be hoped that in the matter of the sewerage of Havant the Local Government Board will take steps to force this Council to carry out its long neglected duty, and further that the state of affairs brought to light in this town will induce the County Council of Hampshire to consider the advisability of providing themselves without delay with a competent medical adviser.

◆

THE clear and identical judgments of Mr. Justice LAWRENCE and Mr. Justice CHANNELL in the important case of HUNTER v. CLARE, the substance of which judgments will be found in a brief report of the case on page 256, leave very little to be desired in the way of exposition. The trouble in this case of dispute about the rightful use of the word "physician" arose—as all the numerous disputes which have been from time to time threshed out in our columns and in those of the lay press about the title of "doctor" have arisen—out of the use of the same words for an academic style and a popular designation. When a man calls himself a "doctor" does he mean simply to convey to the public that he follows the profession of healing and is consequently applying to himself the colloquial title by which members of the profession of healing are known to the public? Or does he mean to arrogate to himself an academic title signifying the possession of a medical degree at a recognised university? In the case of the title of "doctor" we have always maintained that the medical man in his professional relations with the public should be most careful only to give himself the style that belongs to his degrees or his diplomas, holding that for a licentiate or a member of a corporation to call himself "doctor" is wrong. In our columns we have supported this view by words and by example, and although now and again we have received protests, based mainly upon one or two unavoidable inconsistencies, we have reason to believe that the profession as a whole take the view which we have put forward. The case of HUNTER v. CLARE reopens—for the point has been debated before—the same question concerning the style of "physician." Who has a right to call himself a "physician"—anyone qualified to practise "physic," or only the possessors of certain degrees or diplomas? We do not now discuss other issues raised by this litigation The reason of the original prosecution of the late Mr. HUNTER and the management of their share in the matter by the General Medical Council are important enough matters, but they have nothing to do with the subject at present under consideration. It is sufficient to remind our readers that Mr. HUNTER was convicted before a bench of magistrates of Cambridgeshire of having wilfully and falsely pretended to be, and taken and used the name and title of, a physician contrary to Section 40 of the Medical Act, 1858. Mr. HUNTER's alleged offence against the Act consisted in calling himself "physician" upon his billheads, his registrable diploma being the Licence of the Society of Apothecaries dated 1893. Against this conviction the appeal which has just been decided was lodged in the name of Mr. HUNTER who has died since the proceedings in the magistrates' court, but supported by the Society of Apothecaries whose Licentiates are nearly concerned. Mr. Justice LAWRENCE and Mr. Justice CHANNELL concurred in finding that Mr. HUNTER, as a Licentiate of the Society of Apothecaries, was not entitled to call himself a physician, but that in so styling himself he had not wilfully misdescribed his qualification; the conviction, therefore, in their joint opinion must be quashed, but the appellant could not be allowed his costs. This is a serious decision for the Society of Apothecaries, many of whose Licentiates are certainly describing themselves as physicians with no idea of wilful deception, but simply because being duly licensed to practise in medicine as well as in surgery and midwifery they consider that they are correct to assume this designation. Those who so interpret the 40th Section of the Medical Act of 1858 must now consider themselves wrong and must understand that the word "physician" has been used in the Medical Act strictly to mean possession of certain degrees or diplomas and not generally to mean possession of a medical qualification.

Annotations.

"Ne quid nimis."

THE PRINCE OF WALES AND THE MEDICAL PROFESSION.

THE occasion of the delivery by Sir William MacCormac of the Hunterian Oration at the Royal College of Surgeons of England this year will be distinguished by the presence of the Prince of Wales who has also graciously consented, at the President's invitation, to dine with the College the same evening. It is not the first time that the Prince of Wales has honoured the Hunterian orator by attending the delivery of the oration. He was present when Sir James Paget and Mr. Bryant were the orators. Nor is it the first time that His Royal Highness has dined with the College, but there are circumstances that make his presence especially gratifying to the College this year. The Prince of Wales has clearly designed to do honour to the medical profession at a time when he has just received the benefits of surgery, while his host on the occasion will be the surgeon responsible for the line of treatment which was then adopted. By the way, the Royal College of Surgeons of England, remembering that the Prince is a Fellow of the Royal College of Physicians of London, may desire to give him the second qualification necessary to registration and elect him a Fellow of the Royal College of Surgeons of England.

METROPOLITAN WATER BILLS.

SEVERAL bills having reference to the London Water-supply have been deposited at [illegible] Bills Office. [illegible] County [illegible] Amongst

Council, one by the East London Waterworks Company, and one by the Metropolitan Water Companies. The titles of the bills are as follows:—1. "A Bill to authorise the Construction of Aqueducts and Works for the Supply of Water to London and neighbourhood; and for other purposes." The short title of this bill is "London Water (Aqueducts and Works)." 2. "A Bill to authorise the Construction of Reservoirs and Works in Wales for the Supply of Water to London and neighbourhood and for other purposes." The short title of this Bill is "London Water (Welsh Reservoirs and Works)." These two Bills are promoted by the London County Council. 3. "A Bill to authorise the East London Waterworks Company to Construct Additional Storage Reservoirs and other Works and to raise further money and for other purposes." The short title of the Bill is "East London Water." 4. "A Bill for Improving and Facilitating Intercommunication between the Mains and Works of the Metropolitan Water Companies." The short title of the Bill is "Metropolitan Water Companies." It is promoted by all the metropolitan water companies. It will be seen that in each case the chief objects of the Bill are clearly stated in its title. The Metropolitan Water Companies Bill came before the Examiner of Private Bills on Monday, Jan. 23rd, and was passed without opposition. The London Water (Aqueducts and Works) and London Water (Reservoirs and Works) Bills have met with considerable opposition at the Private Bills Office. The Welsh Reservoirs Bill has been opposed by a memorial presented by nearly a hundred signatories and five sittings have already been held by the Examiner of Private Bills to consider the technical bearing of the allegations made against it. In some cases the Examiner found that notice had not been given to owners of property affected by the scheme. In one rather curious case a notice had been served on one John Jones who was not the owner of the property with the possession of which he was credited. He was by no means the only man of that name in the district, and the estimated number of John Joneses varied from three to five. In this case the Examiner thought the wrong gentleman had obtained the notice by misadventure and that the promoters of the Bill were not to blame. Four memorials have been presented against the London Water (Aqueducts and Works) Bill; amongst the memorialists are the Middlesex County Council.

DO WOMEN BEAR ABDOMINAL OPERATIONS BETTER THAN MEN?

THIS is pre-eminently the age of *statistics*. Of late years so much care, ingenuity, and industry have been devoted to the compilation of tabular statements affecting pretty nearly every subject under the sun that averages alone have come to be esteemed as worthy of notice, the salient instances by which public opinion used formerly to be in a great measure formed and guided being now regarded as of no more value than any other of the similar but obscure items in the same category. It would be difficult to find a subject in either medicine or surgery which has not been exposed to the test of figures and especially is this the case with regard to operations. Amongst other points all more or less noteworthy the influence exercised on the results of surgical interference by age, temperament, nationality, latitude, season, the experience of the operator, &c., has been statistically recorded with much advantage, while incidentally these investigations have likewise been by no means barren. For some considerable time the supposition that grave surgical operations were better supported by women *than* by *men* was rather extensively entertained, but it was not until totals had been systematically tabulated that we were afforded reliable grounds for believing that members of the so-called feebler sex could endure the knife with greater advantage than those of the sex which is inured to labour and hardship. The following figures, supplied by *Haberkant* and quoted by Professor Tarnier in a lecture last summer, would certainly seem to afford *primâ-facie* evidence of the exactitude of the proposition. In 117 cases of gastro-enterotomy in the male there was a mortality equal to 54 per cent., while in 96 similar cases in the female it was only equal to 35 per cent., a difference of very nearly one-fifth. In pylorectomy the discrepancy was not quite so prominent, the mortality after 70 operations in the male and 140 in the female being at the rate respectively of 64·3 and 52·8 per cent., an advantage in favour of the latter of only 11·5 per cent. As may be supposed a great many theories have been advanced in explanation of this sexual peculiarity. In the opinion of one profound observer who has actually been bold enough to place his lucubration on record in print women *suffer* less than men after capital abdominal operations because it is especially characteristic of this sex to enjoy this comparative immunity. As Professor Tarnier did not fail to remark, this intelligent explanation reminded him of the well-known character in Molière who so strenuously maintained that opium caused somnolence because it was endowed with soporific properties! According to Dr. Marcel Baudouin, however, it is not impossible to furnish reasons which at all events are plausible for the fact that females support operations better than males. In the first place, pregnancy makes the abdominal parietes thin and flaccid, thus enormously favouring examination and consequently helping to an accurate diagnosis. Secondly, women are more prone to complain than men, especially in connexion with anything that concerns their reproductive systems. In this way their cases come under observation *at an early stage* when surgical interference is less of a *pis aller*. Thirdly, men as a rule hate confinement, whereas *women are accustomed* to an indoor life. Fourthly, women do not smoke or drink and nature consequently can exert her *recuperative qualities* more effectually.

UNFIT HOUSES.

IT will be remembered that Mr. Gilbert's Lord Chancellor used to sing nightly, "The law is the true embodiment of everything that's excellent; it has no single fault or flaw." Be this as it may, the law is constantly providing the most eccentric situations, and one of these has just occurred in the Borough. In 1895 some cottages in Red Cow-alley were closed by order of the magistrates and were dismantled but not pulled down. Dr. Waldo (medical officer of health for St. George-the-Martyr, Southwark) then urged that the old buildings and drains were a source of danger to public health and that the site ought to be cleared. The vestry accordingly made an order for demolition under the Housing of the Working-classes Act, 1890. The owners of the property appealed and the case was heard at the South London Sessions on Jan. 13th. After a long hearing the court decided against the order but agreed to state a case for a higher court. The court held that the houses were uninhabited and consequently not dwelling-houses within the meaning of the Act of 1890. Counsel for the owners of the property said that a dwelling-house was defined as an inhabited building. Counsel for the vestry argued that the word "building" used in Section 33 of the Act meant a closed dwelling-house. Therefore the position would seem to be as follows. To pull down a house under the Housing of the Working-classes Act it must first be closed. Unless somebody, owner or tenant, is enclosed too the building ceases to be a dwelling-house because nobody dwells in it. Then it cannot be demolished under an order for dealing with dwelling-houses. Truly a fit *motif* for a Savoy opera. We shall await the decision of the High Court with interest Possibly, again to quote Mr Gilbert s Chancellor, the court will find that the insertion of a "not" will meet all difficulties If it were required that a house should not be a dwelling house before it could be pulled down matters might come all right

A NEW PROTEID IN MILK

To the three proteids already known to exist in milk—albumin, globulin and casein—a fourth must now be added which has been named by its discoverer, A Wróblewski, "opalisin", from the opalescent appearance of its solutions M Wróblewski has given a description of it in Hoppe Seyler s *Zeitschrift für Chemie* It exists in largest quantity in human milk, a similar if not identical substance is less abundant in the milk of the mare, and there is yet another which, however, only exists in very small quantities, in the milk of the cow Its percentage composition is —C, 45 01, H, 7 31, N, 15 07, P 0 80, S, 4 70, and O 27 11 This new proteid does not reduce Fehling s solution after boiling with hydrochloric acid and it yields no pseudonuclein when digested with pepsin For the solution of one gramme 121 3 c cm of a solution of soda containing 1 part of the alkali to 100 parts of water are required It responds to the biuret, Millon and xanthoproteic tests and also to that of Adamkiewicz It was obtained by the addition of sodium chloride to the fluid remaining after the precipitation of the casein in human milk by hydrochloric acid

THE APPOINTMENT OF COUNTY MEDICAL OFFICERS OF HEALTH

THE subject of the appointment of county medical officers of health bids fair to become a question as perennial and as strenuously fought as that of vaccination Although, however the northern counties have supplied by far the greater number of conscientious objectors they are in many cases ahead of the south in the matter of the appointment of county medical officers of health, and in our issue of Nov 26th we compared Lancashire, Durham, and the West Riding which had appointed county medical officers with counties such as Somerset Devon, and Cornwall which had not We are glad to see that the Wiltshire County Council decided recently to appoint a county medical officer but this very sensible resolution seems to have raised the ire of the district councils and at a meeting of the Salisbury District Rural Council held on Jan 6th a request was considered from the Devizes Rural District Council inviting the concurrence of other district councils to memorialise the county council against the appointment After a great deal of argument it was agreed by 19 votes to 3 to comply with the request of the Devizes Council Mr Robinson is reported as saying that ' what they wanted was a sanitary surveyor not a medical officer full of whims and fads who would not allow them to call their souls their own ' Mr C Drake thought the appointment of a county medical officer would tie their hands If there were any wells which required to be seen to or nuisances to be abated it was the duty of individual councillors to call attention to them and it was rather a slur on them if they did not do this To take another county the motion to appoint a county medical officer for Somersetshire has been defeated, and during the debate it was argued that medical practitioners with incomes of £1000 a year would not submit to being "bossed by an officer only receiving £500 We cannot believe that any district medical officer would be so silly as to say a thing like this nor can we understand how any councillor could be influenced by such an argument There is one simple way out of this difficulty and that is to give the county medical officer £1000 a year instead of £500 There cannot be the least doubt that an administrative county should have a county medical officer, and as we have previously said[1] he must not only be specially qualified but be granted a salary giving him the necessary status of a county official Otherwise he will either not be able to maintain the position necessary to his proper influence or he will use his post as a mere stepping stone to higher things The appointment of a county medical officer in the enjoyment of good salary and *pari passu* debarred from private practice is most valuable He is not exposed to local jealousies, he can act without fear or favour, and his advice is often most valuable both to his own council and to the various district medical officers of health who can and do seek his advice upon matters connected with the sanitary administration of their various districts knowing that his influence may very probably further objects which they have greatly at heart but to carry out which they are practically helpless owing to the clashing of different interests and also because some of the owners of property whose interests are involved may very possibly be the private patients of the said district medical officers Decentralisation is all very well but in sanitary matters as in everything else there must be a central head

A MODIFICATION OF LABORDE S METHOD OF RESUSCITATION IN DEEP ASPHYXIA

AT the meeting of the Académie de Médecine of Paris on July 5th, 1892, Laborde demonstrated his method of resuscitation in asphyxia by rhythmical traction of the tongue He recommended that the tongue should be seized firmly and that traction should be made about 20 times a minute In the *New York Medical Journal* of Dec 10th 1898 Dr W Freudenthal suggests a modification of this method He considers that the effect is due to stimulation of the sensory nerves of the tongue and indirectly of the epiglottis and that a greater effect can be produced by direct irritation of the epiglottis He tested this view in the following case A tuberculous man, aged thirty eight years underwent operation for an abscess in the neck He was in deep narcosis and the incision had just been made when the respiration and heart s action almost simultaneously ceased Attempts at resuscitation were made until the operators were nearly exhausted Then, with the patient s head hanging over the edge of the table and his jaws separated by a gag the index finger was moved to and fro over the epiglottis After a short time he commenced to swallow and then to breathe, only to stop two minutes later A second and a third "tickling had the same effect After the last the pulse and respiration remained normal

THE APOTHECARIES SOCIETY AND THE PHYSICK GARDEN

AT last it would seem after the many rumours which of late years have gained currency to the effect that the Society of Apothecaries were contemplating the sale of the old historic Physick Garden botany being no longer a necessary part of the medical curriculum, that the garden is to practically pass from the control of its former custodians into the hands of the Charity Commissioners This new committee of management will consist of 15 persons nominated by the London Parochial Charities Trustees, the Treasury, the Royal Society, the Society of Apothecaries the Pharmaceutical Society of Great Britain and other public bodies, and the garden is to be maintained for promoting the study of botany with special regard to the requirements of (*a*) general education, (*b*) scientific instruction and research in systematical botany and vegetable physiology, and (*c*) instruction in general pharmacy as it concerns the culture of medicinal plants The scheme also provides for the erection of new offices, lecture rooms, and a physiological laboratory, the appointments of a curator and a head gardener, the establishment of lectures upon botany, and the maintenance of collections of living plants for teaching purposes. The students and professorial staff of the Royal College of Science are to be accorded free admission into the garden, with use of the collections, lecture-rooms, and appliances, so long as the sum of £150, or more, shall be paid in that behalf to the Trustees of London Parochial Charities, as trustees of the remodelled charity. The scheme seems to us one which should be productive of much good, but as our lay contemporary the *Gardeners' Chronicle* points out—

---

[1] THE LANCET Nov 26th 1898 p. 1414

> "The medical profession till lately furnished the great majority of our botanists. They took service in India and the colonies, took part in exploring expeditions, and they contributed enormously to our knowledge of the botany of the globe. It is to be feared that the medical men of the future will not be so well equipped for this purpose as their predecessors were, and that systematic and economic botany will suffer proportionately."

We hope, however, that the medical profession will still maintain its interest in Sir Hans Sloane's old legacy and will also continue to receive the encomiums which it has earned in the past with regard to botanical research.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

ON Thursday last, Jan. 19th, a well-attended meeting of the Metropolitan Hospital Sunday Fund was held at the Mansion House when, in the absence of the Lord Mayor, the Earl of Stamford presided. Among those present were Mr. Astley Bloxam, F.R.C.S., Canon Rhodes Bristow, Mr. T. Bryant, F.R.C.S., Mr. A. L. Cohen, Sir Edmund Hay Currie, Mr. George Drummond, Dr. Glover, the Rev. C. H. Grundy, the Right Hon. William Lidderdale, Mr. T. Mackrell, Captain A. Palliser, and Mr. Wakley, F.R.C.S. The solicitor to the Fund, Mr. Cheston, stated with reference to the Vokins bequest that under Mr. William Vokins's will the Fund would benefit to the amount of some £49,000 Consols, the market price of which amounted at the present rate to about £55,000. Sir E. Hay Currie expressed the indebtedness of the Fund to Mr. Cheston for the valuable time he had devoted in connexion with this magnificent legacy and expressed the hope that Mrs. Vokins's death might long be deferred. Viscount Falkland was nominated a member of the council in the room of the late Earl of Strafford, but the deaths of Lord Charles Bruce and Dr. C. J. Hare and the resignation of Canon Eyton still leave vacancies on the council. The general purposes committee were re-elected, and the distribution committee for the year was constituted as follows:—The Lord Mayor, Sir Savile Crossley, Captain Cundy, Mr. Robert Grey, Mr. Herman Hoskier, Mr. Lidderdale, Mr. F. H. Norman, Dr. Sedgwick Saunders, Sir Sydney Waterlow, and Mr. Alfred Willett. Sir E. Hay Currie and Mr. R. B. Martin, M.P., were re-elected honorary secretaries, and Messrs. W. H. Pannell and Co. were appointed honorary auditors.

THE LEBANON HOSPITAL FOR THE INSANE.

ABOUT two years ago Mr. Theophilus Waldmeier inaugurated a movement the object of which was to provide an institution for the reception of insane persons in Syria and Palestine. Up to that time no steps whatever had been taken for the proper care and treatment of these unfortunate persons, many of whom are left to wander about at will whilst others whose condition does not permit them to go free are removed to monasteries, caves, and churches, where they are chained up and badly fed. The chief form of insanity acknowledged in the East is demoniacal possession and therefore the proper persons to treat those afflicted are thought to be the priests who cause the sufferers to go through all sorts of tortures in order, as they say, to "drive the devil away." Mr. Waldmeier having had thirty-eight years' experience amongst the inhabitants of the East, mostly Syrians, is well acquainted with the condition of the people and he relates an instance in which an insane woman was at the request of her relatives treated by a Maronite priest who caused her to be placed on her head whilst two men held her body straight up and she was bound with ropes to a pillar. The priest read the formula of exorcism and burnt incense in a censer, at the same time commanding the demon to depart, and on the woman becoming excited he struck her on the face with a large silver cross until the blood flowed. Eventually she drowned herself in the sea. It was estimated that at least £10,000 would be required for the establishment of a proper asylum in Syria or Palestine and Mr. Waldmeier spent much time in travelling in various Continental countries, in Great Britain, and in America in order to arouse interest in the cause. When about £4500 were collected the committee at Beirut selected a very suitable site of about 30 acres at Asfuriyeh, 3¾ miles from Beirut. The four medical members of the committee, Mr. Brigstocke, Dr. Graham, Dr. Van Dyck, and Dr. Wortabet, have visited it together and have reported favourably upon it. The committee have issued their first annual report and they make an earnest appeal for subscriptions which may be sent either to Sir Richard Tangye, the treasurer, or to Mr. Francis C. Brading, the secretary, at the offices of the committee, 35, Queen Victoria-street, London, E.C. The chairman of the central committee is Dr. R. Percy Smith, late of Bethlem Royal Hospital.

FRANKS *v.* HARGREAVES.

AN action was tried in the Queen's Bench Division before Mr. Justice Mathew in which a carpenter named Franks sued Dr. M. K. Hargreaves of Wimbledon for negligence. The plaintiff sustained a fracture of his right leg for which he was treated by the defendant with the result that five-eighths of an inch of shortening took place. The plaintiff alleged that the defendant had treated him as if one bone alone were broken, whereas two had been broken, and he therefore claimed compensation. The defendant said that he considered that only the tibia was broken. An x ray photograph, however, was put in showing a fracture of both tibia and fibula. One medical man said that in his opinion the treatment had been unsatisfactory, while others gave evidence to the contrary. Mr. Justice Mathew said that medical men were not responsible for errors of judgment if they honestly tried to do their best and the jury found for the defendant. This was an eminently sensible finding. "None of us," to quote the late Master of Trinity, "is infallible, not even the youngest," and medical men are no exception to this rule. Neither, as the householder knows, are carpenters. We do not deny that Dr. Hargreaves made a mistake in diagnosis, but the treatment for a fractured tibia is practically the same as that for a fracture of both bones of the leg. Therefore the defendant was not injured by the wrong diagnosis. A medical man's life is hard enough without, as Mr. Justice Mathew remarked, his being exposed to the prospect of an action at law for every mistake which he may make.

DIPHTHERIA ANTITOXIN AS A PROPHYLACTIC.

IN *Treatment* (Jan. 12th) Dr. F. J. Allan, medical officer of health of the Strand District, narrates a personal experience which illustrates the immunising action of antitoxin in an institution accommodating 60 children varying in age from one and three-quarters to seventeen years. Most of them slept in two large, airy dormitories and the classrooms occupied during the day were also large rooms. Early in February, 1898, one of the children, during a visit to a friend, was exposed to infection from a case of diphtheria, and on returning home on the same day developed the disease herself and communicated it to the girls in the beds on each side of her own. These 3 cases were removed to a hospital and no further cases appeared until a few days after their return home in the beginning of March. By March 23rd 5 cases had occurred in the same dormitory and a bacteriological examination of the throats of the 3 former cases revealed the fact that 2 of them contained typical diphtheria bacilli. Up to April 29th several other children developed the clinical symptoms of diphtheria and several more had inflamed throats without membrane. On April 29th at Dr. Allan's suggestion a protective dose of antitoxin was given all round, and from that day, although the organisms persisted in the throats, there were no more cases of diphtheria or of sore-throat. Of the 60 children, 9 only never gave evidence of infection, 14 were in hospital, leaving 34 children at home in addition to the first 3 returned from hospital. As time went on the organisms in these 37 throats became less and less typical in form, and by June 15th all had disappeared. The immunising dose of antitoxin is from 100 to 300 units, according to age, and the immunity thus produced ordinarily lasts for a period of at least four weeks.

AN IMPERIAL UNIVERSITY FOR INDIA.

WE are informed that owing to the munificent offer of a rich Parsee in Bombay there are great prospects of a scheme for the establishment of an Imperial University for India being completed at an early date. It is not proposed to run counter to any existing university, but the scheme is solely for the development of post-graduate education in the higher scientific and technical branches of learning. The medical and allied sciences are well provided for. Mr. Jamsetjee N. Tata offers a property representing a capital of over £200,000 and calculated to yield a yearly income of nearly £10,000 for the establishment of an Imperial University or a Research Institute in order to supply the want of a higher course of post-graduate instruction in scientific research for the best students of the existing universities. Mr. Tata seems to recognise that the industrial development of the country can be best furthered by training graduates in the higher branches of scientific research. A provincial committee has been formed which has drafted a Bill for the approval of the Government of India. It recently laid its plans before the new Viceroy with the hope of obtaining his support. In the scheme of studies there will be a threefold division—(1) scientific and technological; (2) medical and sanitary; and (3) educational and philosophical. The last of these branches has been included in the scheme in order to give the institution the character of a university. The new institution seeks to have the power of granting degrees and diplomas, and as it proposes to offer a strictly post-graduate course of studies it will not in any way interfere with the working of any of the existing universities. The scheme of the provisional committee involves an expenditure larger than is provided for by Mr. Tata's generous offer. A grant in aid therefore will be asked for from the Government of India. The support of native princes, of local governments, and of the public generally will also be sought. It is estimated that the initial expenditure required will amount to over £100,000 and the annual charge to about £20,000. On this basis, therefore, it is proposed to establish the several departments by degrees and to found subsequently special chairs through public and private munificence. There is already a large fund promised or collected for the Jubilee Health Institute initiated by his Highness the Maharajah of Dholpore and to this some of the native princes have made large contributions. The object of that institute is chiefly bacteriological research and it thus falls within the second of the three departments of studies included in the draft scheme. It is hoped, therefore, that the funds of the two institutes may be consolidated. Besides the Health Institute there are considerable funds raised in the Punjab and Hyderabad (Deccan) for research purposes and for the promotion of higher scientific education. A hope is expressed that those supporting this proposal may also join Mr. Tata's scheme. Altogether, it may be said that not only is the offer a grand one, but that the scheme is a grand one as well as being comprehensive. That the industries of the country will be developed there can be little doubt. Sufficient students for the various branches will also probably be forthcoming as time goes on, for it must be remembered that unless the country develops the capacity for absorbing their services there will be a limited demand for highly trained technical graduates and consequently there must in the long run result a falling off in the number of students. The above scheme of a separate university or institute open to the graduates of all existing uuniversities and fully equipped with the necessary staff of teachers and appliances, such as laboratories, museums, libraries, &c., has already received the concurrence of Lord Sandhurst, the Governor of Bombay. Special legislation by the Supreme Council will have to be undertaken as the power of control and regulation is in the ultimate resort left to the Government of India. The institution will be imperial in character. The only doubt which suggests itself at first thought is that if the larger scheme absorbs the smaller institutes of bacteriological research and of public health or the proposed Pasteur Institute for India the objects of the latter undertakings may suffer in consequence. Popular misapprehension or popular feeling might make itself felt in a large institution governed to a certain extent by the popular will to the detriment of experimental science and bacteriological research. Before the Government of India gives its sanction to the scheme it is to be hoped that it will secure that the medical sciences shall not be hampered by any sentimental opposition to experimental investigations and that the object of the smaller institutions shall be thoroughly secured. At present, however, nothing is settled but we can at least recognise, as Lord Curzon of Kedleston said o receiving a deputation, the great generosity and public spirit which Mr. Tata has shown in contributing so magnificent a sum for the promotion of a great public purpose.

THE PLAGUE IN HYDERABAD STATE: A REPORT BY LIEUTENANT-COLONEL LAWRIE, I.M.S.

AN account has reached us of experiments made on the manner in which the plague may be spread amongst the inhabitants of an infected district. The report is issued by Lieutenant-Colonel E. Lawrie, I.M.S., Residency Surgeon at Hyderabad, is addressed to Mahomed Aziz Mirza, secretary to H. H. the Nizam's Government, Hyderabad, and is dated Sept. 12th, 1898. It contains a brief record of an investigation carried out in the temporary laboratory of the Hyderabad Medical School into the bacteriology of a virus found in the floor dust and scrapings of houses infected with plague in the Dominion of Hyderabad, and its substance has been made public in England by the accounts of Lieutenant-Colonel Lawrie's evidence before the Plague Commission.[1] To the report are appended the diary of the laboratory kept during the inquiry; a note by Surgeon-Captain Johnston, I.M.S.; and two memoranda by Mr. Stevens, Deputy Plague

[1] See THE Jan.

Commissioner, on the methods of detecting the infection of plague in soil and of destroying it by the kiln process of burning. A microbe, closely resembling the plague microbe was discovered in the surface scrapings of the floors of all the infected houses throughout the villages in which cases of plague had occurred. At first the attempt was made to destroy the infection in the floors by burning grass or cowdung and kerosene oil on them, but this plan proved uncertain, inefficient, and dangerous, and ultimately the kiln method of burning the dug-up floors was decided upon. Experiments were also made by which it was desired to prove that the microbe found in the surface of the floors of houses infected with plague was the true plague bacillus. Lieutenant-Colonel Lawrie sums up the practical value of the knowledge that the plague virus lodges in and is disseminated through the floors of houses as follows: 1. The infection of plague can be tracked about by means of the microscope with as much certainty as if it were visible to the naked eye. 2. The value of disinfection can be measured by the same means. 3. The one disinfectant with which uniform results are obtained is fire. When a mud floor is reduced to ashes by the kiln process of burning no trace of the microbe can be discovered in the ashes. 4. By means of the microscope, fire, and boiling, plague can be stamped out with nearly mathematical certainty. 5. Floors and clothing contain the food by which the plague microbe is kept alive; their disinfection by fire and boiling destroys the food-supply of the infection.

JOINT DISEASE IN INFANTS DUE TO OPHTHALMIA NEONATORUM.

IN a paper read before the Royal Medical and Chirurgical Society at the last meeting, held on Jan. 24th, Mr. Clement Lucas directed attention afresh to an original observation which he made in the year 1885, that the purulent ophthalmia of new-born infants was liable in certain instances to produce inflammations of joints similar to the gonorrhœal rheumatism of adults. Mr. Lucas, in the year alluded to, published 3 cases in support of his views and in his first communication, published on Feb. 28th, 1885, he made the following statement: "I am not aware that any connexion between ophthalmia neonatorum and synovitis has ever been observed or described; but there seems no just reason, if, as is generally supposed, the synovitis of gonorrhœa is the result of absorption of morbid products from the urethral mucous membrane, why the conjunctival mucous membrane should not offer an equally favourable absorbing surface. It is scarcely probable that the inflammation of these two joints could be referred to any other cause, and in my own mind there exists no doubt whatever that this is a case of gonorrhœal rheumatism consequent upon absorption from the conjunctival surface." Little attention appears to have been paid to the observation in this country, but abroad it was at once recognised as a form of joint inflammation in infants previously undescribed, and Mr. Lucas was able to found his recent paper upon 23 published cases. The correctness of the clinical observation has been submitted to bacteriological proof. Darier in 1889 found the gonococcus of Neisser in the secretion from the conjunctiva, and Deutschmann in 1890 by aspirating the inflamed knee of an infant three weeks old suffering from purulent ophthalmia was able to show the presence of the gonococcus in the secretion taken from the joint, thus completing the chain of evidence. Mr. Lucas shows that the date at which the joint inflammation most commonly appears is at the end of the second week or during the third week of the ophthalmia. The joints most liable to be affected are the knees and wrists, more especially the left; but any joint may be attacked and in some cases the tendon sheaths have shown signs of inflammation. Although the inflammation may be intense there is little tendency to suppuration and when it occurs Mr. Lucas asks the interesting question as to whether another microbe may not be associating its effects with the gonococcus, for in two cases in which suppuration took place the gonococcus was found to be associated in one instance with the staphylococcus and in another with the streptococcus. In reference to treatment Mr. Lucas suggests that as the infecting source is the conjunctiva the most important thing is rapidly to disinfect this mucous surface and with the cure of the ophthalmia the joint inflammation will generally rapidly subside.

THE ADULTERATION OF FOOD.

THERE is distinct promise of the subject of food adulteration being seriously dealt with in the forthcoming session of Parliament. Such at least is the assurance contained in a speech delivered by the Minister of Agriculture, Mr. Walter Long, at a political meeting in Bath on Jan. 23rd. He said that he believed there was great truth in the statement that there was wholesale adulteration going on in the country and he was to be responsible during the session for the introduction of a Bill which he hoped would reduce adulteration. We trust that the terms of this Bill will be much in line with those of the excellent measure which was introduced in January, 1897, by Mr. Kearley and which was dealt with at some length in a leading article in THE LANCET of March 6th, 1897.

THE DANGER OF LONG HOURS IN DRUGGISTS' SHOPS.

AN agitation has been set on foot in New York to reform the drug business in that city. An organisation entitled the Druggists' League for Shorter Hours of Labour has recently held a meeting at the Judson Memorial Church where the speakers sought to demonstrate that the public should be quite as interested in this matter as the members of the trade. It was even urged that the grand jury should institute an official inquiry concerning the abnormal conditions of a trade conducted to the "detriment of public morals and to the danger of public health." The grand jury has the power to make such representations to the Legislature as the facts may warrant. It is admitted that numerous errors have been made in the compounding of drugs. These blunders are attributed to the exhaustion consequent on prolonged hours of labour. The grievance is so far admitted that a Bill has been introduced in the Albany Legislature by which no one engaged in the making up of medical prescriptions shall be allowed to work more than ten hours on week days except Saturday, when he may work for twelve hours. On Sundays and legal holidays it is proposed to allow six hours' work. The druggists agree that when accidents have occurred and mistakes been committed they were almost always attributable to some overworked person who had perhaps been led to employ morphine, cocaine, and other drugs to stimulate his flagging energies. During the four years ending July, 1898, 13 dispensing assistants in drug stores committed suicide and 7 others attempted but failed to kill themselves. These suicides were the consequence of the physical conditions induced by the taking of drugs to resist the effects of fatigue. In 1897 there were 13 deaths reported as due to the mistakes of druggists and it is probable that many more such deaths have been hushed up. The druggists sometimes pay very large sums to their customers when through some blunder a person is poisoned and thus the cases do not always come before the courts. In the face of these statements it does seem as if the Assistant Druggists' League have a good case. Overwork is always injurious to the person who suffers from the strain, but sometimes it is also dangerous to the public, as in the case of engine-drivers and railway signalmen. On their alertness the safety of the travelling public depends. The same may be said with regard to the dispensers of medicines. The slightest carelessness or inattention may result in fatal consequences and it certainly is to the interest of the public to see that the dispensers of medicaments enjoy sufficient leisure and rest.

TETANUS IN OBSTETRIC CLINICS.

ACCORDING to the *Allgemeine Medicinische Central-Zeitung* the Obstetric and Gynæcological Clinic attached to the Bohemian Medical Faculty of the University of Prague has for some time past been visited by an epidemic of tetanus which has proved fatal to many of the patients and which the most stringent hygienic measures, including the use of antitoxin, have failed to stamp out. Indeed, the epidemic has recently spread to two other obstetric institutions in the city—viz., those connected with the Midwives School and the German University Clinic.

THE OPERATIONS IN UGANDA.

IN the list of appointments and promotions just published in the *London Gazette* in recognition of the services of officers during the recent operations in Uganda we are very glad to notice the names of the following medical officers upon whom the Queen has been graciously pleased to confer the Distinguished Service Order: Captain G. S. McLoughlin, M.B. Durh., and Captain J. D. Ferguson, both of the Royal Army Medical Corps. We heartily congratulate these officers on the distinction which they have won

ACCESSORY THYROID BODIES AT THE BASE OF THE TONGUE.

AT a recent meeting of the Pathological Society of Philadelphia Dr. H. L. Williams presented two cases of this rare anomaly. A woman, aged fifty years, complained of a growth at the base of the tongue which she had had for eight or ten years without much inconvenience but which had begun to enlarge and to produce dyspnœa and difficulty of speech It lay in the median line just above the epiglottis. The growth was about 1¼ in. in width and 1 in in thickness, oval, rounded, and smooth on the surface, except at the top where it was superficially ulcerated and covered with a whitish membrane A small portion was removed and showed microscopically in addition to the signs of inflammation typical thyroid structure containing colloid material In the second case the patient was a young women, aged sixteen years, who had a growth at the base of the tongue for five years which had recently enlarged causing some dysphagia. It was situated in the same position as the growth seen in the first case. On removal by the wire cautery it measured 1⅛ in in length, 1 in in width, and ¾ in. in thickness It was soft and spongy in appearance, surrounded by a fibrous capsule, and showed a delicate reticulum of fine filaments extending through it in all directions The surface was reddish, in some areas whitish, glistening, and resembled the thyroid gland. Microscopically a meshwork of acini separated by a delicate reticulum of connective tissue was seen. The acini were almost invariably dilated and cystic and filled with colloid material The diagnosis of cystic thyroid tissue undergoing colloid degeneration was established Thyroid tissue at the base of the tongue is readily explained embryologically. The middle thryoid area first appears as a ventral outgrowth from the entodermic lining of the primitive pharynx at a position corresponding to the second visceral arch. This outgrowth rapidly elongates and generally loses its attachment with the epithelium of the pharynx, the connexion being represented by a fibrous band (thyroglossal duct) which emerges from the tongue at the foramen cæcum. When thyroid tissue is found in this locality it is formed from embryological remnants at the upper extremity of the thyroglossal duct.

SIR WILLIAM CROOKES AND MICROBES IN THAMES FLOOD WATER.

A DIAGRAM exhibited by Sir William Crookes at the forty-fourth meeting of Lord Llandaff's Water Commission appears to have misled or perplexed the Royal Commissioners. We are aware of the difficulty sometimes experienced by men of science in explaining technical details in such a way as to be comprehensible to lay minds and we should therefore be glad to publish Sir William Crookes's diagram with any explanation of it which he may be pleased to give should he wish to have the matter further elucidated.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

THE annual subscribers to the College now number, we are informed, 320 and applications for enrolment are coming in The life governors, donors, and guarantors already constitute a considerable body. The organisation of the College has been delayed from various causes, but we understand that it is being pushed forward as rapidly as possible and that no pains will be spared to supply the varied needs of the practitioner. The authorities state that as the work will be continuous throughout the year and the teaching thoroughly practical medical men will be able at any season to perfect their technical skill and to enlarge their professional knowledge The medical superintendent will be happy to receive any medical visitor to the College (22, Chenies-street, W.C.) who may desire further information. The first general meeting of the governors was held on Thursday evening last at 5 P.M.

THE POSITION OF NURSES IN POOR-LAW INFIRMARIES.

AT the meeting of the London and District Poor-law Officers' Association held at Hackney on Jan. 20th Miss E Julian, the Matron of the Croydon Infirmary, read a paper on the Need of Nursing Reform in Workhouse Infirmaries. It is well known that since the Order of the Local Government Board prohibiting pauper nursing in infirmaries the Poor-law authorities have been put to great straits to obtain duly trained and qualified nurses. Miss Julian asks why should this be when everyone knows that there are plenty of trained nurses in want of work. She finds her answer, to use her own words, in "loss of professional status, lack of adequate assistance, the monotonous home life, and uncongenial surroundings." It must be remembered, too, Miss Julian goes on to say, that there is a popular idea to the effect that a workhouse nurse is a woman not sufficiently refined to be employed in a hospital and this idea is not confined to laymen alone. The superintendent nurse has but inadequate assistance and has no voice in the selection of her assistants and also she is practically cut off from society. Compare her position, says Miss Julian, with that of the matron of a provincial hospital. Two remedies have been suggested for this unhappy state of matters—one, that the Poor-law nursing service should be a department of the State as are the Naval, Military, and Indian Nursing Services; the other, that the large Poor-law infirmaries should train nurses for the smaller. This latter suggestion was formulated by Miss Gibson, the matron of the Birmingham Workhouse Infirmary and a paper dealing with the matter from this point of view was read by Miss Wilkie, superintendent of the Halifax Infirmary at the Yorkshire Poor-law Conference held in November, 1898. Miss Wilkie proposed that a nurse should have no salary during the first two years of her training, which is to last four years, but only board, lodging, and washing; and scholarships might be established. Miss Julian apparently advocates a fusion of both schemes, only she thinks that possibly the best thing would be a departmental inquiry into the whole question. It seems to us that most of the difficulties arise from the unfortunate position which the workhouse holds in our social economy. Instead of being, as it ought to be, a place where the really deserving poor can end their days in comfort—a resthouse in short and not a workhouse—it has come to be looked upon as a place of disgrace and discomfort. And this idea is by no means an unreasonable one. Until some method is devised for separating the really deserving poor from the idle, the incompetent, and the loafer, so long will the provision made by the Poor-laws for the poor be considered a thing to be only accepted in the very last emergency. We are far from saying that the tramp, the idler, and the drunkard should be allowed to starve, but there should be some definite line of demarcation between the sheep and the goats, and if this consummation were to be brought about the really deserving poor could be housed in some institution of the bede-house type and the undeserving in a place where they might expiate their sins of omission or commission while those who looked after them would have the same status as the present prison officials, one far superior to that of the workhouse official as constituted nowadays.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

THE winter session of afternoon lectures and demonstrations by the staff of the hospital will commence on Wednesday next, Feb. 1st. The opening lecture of the session will be delivered by Sir R. Douglas Powell, Bart., M.D. Lond., on that day, at 4 P.M., the subject being "Mitral Stenosis." The lectures are free to all qualified medical practitioners and to students attending the practice of the hospital and every care is taken that an exactly typical set of cases shall be at hand for clinical demonstration. We have sometimes wondered whether medical men quite appreciate the opportunities which are thus afforded them of seeing in the brief space of an hour or so a series of examples of thoracic conditions most difficult occasionally to diagnose and of hearing the signs and symptoms expounded at the same time.

"HERPETIC FEVER."

AT the meeting of the Société Médicale des Hôpitaux on Dec. 16th, 1898, M. L. Rénon related the following curious case. A girl, aged eight years, was suddenly seized with headache, nausea, and cough. On the following day the temperature was 100·4° F. and the pulse was 120; there were some white points on the right tonsil and the pharynx was a little reddened. There were bronchitis and a distinct zone of congestion at the base of each lung. The child complained of intense supraorbital headache. Influenza was diagnosed. On the third day there were numerous herpetic vesicles around the mouth and on the right cheek; there were also some on the point of the tongue, the soft palate, and the right tonsil. The general condition was better, the temperature had fallen to 98·6°, and the signs of bronchitis had disappeared. It was evident that the disease was not influenza but an infection which had attacked the respiratory and digestive organs and terminated in an outbreak of herpes. Herpetic fever was diagnosed. On the fourth day the general condition was very good except for some nausea; fresh vesicles were seen on the left cheek, below the eyebrows, in the mastoid regions, and on the left index finger. The latter consisted of a group of three vesicles on the dorsal aspect of the last phalanx immediately below the nail. This group was very painful. There was no albuminuria. On the sixth day there were two new vesicles on the left cheek and three on the right eyelid. The other vesicles were completely dried up except those on the index finger which were very large and very painful. Recovery was not complete until the twenty-fourth day. The interest of this case lies in the localisation and persistence for twenty-one days of herpetic vesicles on the left index finger. Herpes of the extremities is exceptional. Recently[1] MM. Kahn and Apert have observed it on the back of the hands and wrists, but then the disease terminated in five days.

THE QUALIFICATIONS OF THE PUBLIC ANALYST.

IT is quite time that the qualifications of the analyst appointed under the Food and Drugs Act should be more clearly defined. At present it is vaguely required of him according to the tenth clause of the Act that he shall be a person possessing "competent knowledge, skill, and experience" as an analyst of all articles of food and drugs. So far there is no diploma or degree officially recognised by which to an extent the competency of the candidate could be adjudged and thus those whose business it is to appoint the public analyst have no standard which might serve as a guide in this matter. It is anomalous, we think, that in one of the most important branches of home administra there should be an office requiring skilled work which ay be filled by a person possessing neither diploma nor degree. The Act states that he must be competent, and our local authorities have little means of being assured upon this important point. We have already expressed an opinion that the best test of a person's competency for the post of public analyst is the thoroughly practical examination held by the Institute of Chemistry of Great Britain and Ireland. The duties of the office essentially require a person of practical attainments in regard to the analysis of food, water, and drugs, and the Fellowship of the Institute of Chemistry is granted to those persons who have successfully passed the examination which is almost exclusively practical, involving nearly a week's laboratory work relating to the subjects indicated. The science degrees of our universities obviously can count for little, since a man may possess a science degree without the slightest conception of the practical analysis and composition of food and drugs. We think the matter calls urgently for the attention of the Local Government Board. Their decision should remove considerable ignorance upon this subject and tend to secure the appointment of a body of competent persons whose important duty it is to protect the public against fraud and largely also to watch over the hygienic interests of the community.

THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

AT a meeting of the council of the above association held at their rooms, 9, Copthall-avenue, E.C., on Jan. 17th, the subject of a central fund for the payment of Poor-law officers' pensions came under discussion. It was resolved that the present system of dealing with the vexed question of superannuation expenses was likely to lead to serious grievances; that it would inevitably result in preventing the increase of Poor-law officers' salaries under any ordinary circumstances; that it would hinder any man of advanced age, however competent, from obtaining an appointment in the service; and that it would be fatal to the chance of any Poor-law officer obtaining another post after having once lost his office. All this would be avoided, it was thought, by the creation of a central or common fund out of the contributions deducted under the present Act from the salaries of Poor-law officers. There is a good deal to be said in support of the contention of the officials in question. It is, however, a question which affects all branches of the service, and it would be advisable that some common action should be taken in the matter either in the shape of a memorial to the Local Government Board or that the question should be raised in Parliament. It is perhaps only natural that matters which concern medical men personally should occupy a prominent place at such meetings, but a subject which much affects Poor-law medical officers (especially those attached to workhouses and infirmaries) at the present moment is the great difficulty in obtaining properly qualified and adequately trained nurses for these institutions. Possibly it will occupy the attention of this useful association on some future occasion.

---

SPEED OF SOUND.

THE last determination of the speed of sound has been made by Mr. A. Leduc, who finds that the rapidity of propagation of sound waves through dry air at 0° C. = 22° F. is 1088 58 ft. per second (*Comptes Rendus*, Dec. 26th, 1898).

THE adjudicators of the Swiney prize at the meeting held in the rooms of the Society of Arts on Jan. 20th awarded the prize for the present year to Dr. J. Dixon Mann, F.R.C.P.Lond., Professor of Forensic Medicine and Toxicology in Owens College, Manchester, for his book on "Forensic Medicine and Toxicology." The prize, in accordance with the will of the testator, is awarded on every fifth aniversary of his death to the author of the best published work on jurisprudence. The prize consists of a silver goblet of the value of £100, with money to the same amount.

AN "Irish Club" has been formed with the object of providing a convenient meeting place in London, affording opportunity for friendly intercourse between Irishmen, visiting the metropolis from Ireland itself, from the provinces, and from abroad. Those of our readers who are qualified by birth or nationality for membership may apply to the honorary secretaries at the Cockburn Hotel, 13, Henrietta-street, Strand, London, W.C. The Irish Club is absolutely non-political and non-sectarian.

SIR WILLIAM MCGREGOR, K.C.M.G., has accepted the post of Governor of Lagos Sir William McGregor is M.D. of the University of Aberdeen and has held various medical appointments in Scotland and the colonies. In 1875 he became chief medical officer of Fiji and in 1877 was appointed Receiver-General of that colony. In 1888 he was made the first Administrator of British New Guinea and in 1895 Lieutenant-Governor of the colony, a post he has held up to the present time.

THE annual dinner of the West London Medico-Chirurgical Society will be held on Wednesday, Feb. 8th, at the Trocadero Restaurant, Piccadilly, W., at 7 for 7.30 P.M. The President, Dr. S. D. Clippingdale, will preside. Professor William Osler, F.R.S., of Baltimore, who has accepted the office of Cavendish Lecturer for 1899 and who was to have been the chief guest at the annual dinner, will be unable to be present.

DR. SIDNEY MARTIN will lecture on Monday evening next, Jan. 30th, at 8.30 P.M., at the rooms of the Royal Medical and Chirurgical Society, 20, Hanover-square, on Tuberculosis. The lecture is the first of three to be delivered under the auspices of the Royal Institute of Public Health, and all interested are invited to attend.

A NEW periodical, to be entitled *International Archives of Leprosy*, is projected. Communications should be made in English, French, or German; if in any other language a summary should be given in one or other of the languages mentioned. Those willing to support this scheme are requested to communicate with Professor Albert Neisser, Breslau, Museumstrasse 11.

A SESSIONAL meeting of the Sanitary Institute will be held at the Parkes Museum on Wednesday, Feb. 8th, at 8 P.M., when a discussion will be opened on the Supply of Water to London by the Welsh Scheme, by Mr. R. E. Middleton, M.I.C.E, M.I.M.E. Tickets for the admission of visitors may be had on application.

THIS (Saturday) afternoon Dr. Sidney Coupland will be presented with a testimonial which has been subscribed for by members of the staff of the Middlesex Hospital and old students of the school. The presentation will take place in the lecture hall at the Medical School at 4 30 P.M.

THE annual meeting of the After-care Association for Poor Persons discharged from Asylums for the Insane will be held at the house of Sir Samuel Wilks, Bart., Grosvenor-street, W., on Monday, Feb. 6th, 1899, at 3 P.M. Sir Samuel Wilks will occupy the chair.

IRISH MEDICAL ASSOCIATION.

REPORT ON THE GRIEVANCES OF THE IRISH POOR-LAW MEDICAL SERVICE.

WE speak in another column of some features of this report which reveals a very sad state of matters. With reference to the abuse of tickets the report says:—

> Tickets are used generally without inquiry, often without necessity, and always without responsibility. Practically they are given to every applicant. Poor-law guardians and other members of dispensary committees have issued tickets for attendance on their own families. Thriving shopkeepers, farmers of a hundred acres of land, persons with many hundreds of pounds on deposit in bank, earners of incomes up to £3 a week, well-to-do pensioners, and such-like people get visiting tickets without question and present them without shame.

Following this are 17 authenticated examples of abuse, of which, perhaps, the most flagrant is No. 17, which is as follows:—

> 17. Brought on a red ticket to meet Drs. —— and ——, who were privately attending the sick person.

A red ticket be it noted implies that attendance must be given at once For a patient to employ two "pay doctors," and to summon his "dispensary doctor" to consult with them is surely the height of impudence. The report proceeds:—

> Among the recipients of dispensary relief there is a large class able to pay moderate fees in proportion to their means who are not only permitted but are even encouraged to pauperise themselves in the matter of medical attendance. They may be counted probably by the 100,000. The Local Government Board should be able to provide a remedy that would prevent this imposture and at the same time protect the *rights* of the sick poor. Visiting tickets are issued improperly for trifling ailments that should be treated in the dispensary. Sometimes tickets are obtained for purposes outside the scope of the Medical Charities Act. Mothers frequently thus relieve themselves of the duty of bringing their children for inspection after vaccination. Tickets are issued to obtain School Board or other certificates. Agents for small insurances cause them to be used for the protection of their companies. But worse than this is the abuse of issuing visiting tickets without necessity at irregular and unreasonable hours By issuing the tickets only at timely hours (except in case of necessity) the sick would be attended more promptly and *satisfactorily* and the doctor would be relieved of much useless and avoidable drudgery. Proper regulations, of course, are necessary, but regulations alone will fail as they have failed in the past.

For instance, the Local Government Board says that persons empowered to issue tickets under the Medical Charities Act cannot delegate the power to others. This regulation is ignored. In one district during the year 1898 1434 tickets were registered. The number issued by members of the committee themselves was 58.

As to travelling expenses :—

> For £108 a year the dispensary doctor is obliged to attend the sick poor among a population averaging 6557 and to travel over an area of 44 square miles. The roads are not made in straight lines and so the area gives no idea of the length of the journeys. In many places the attendance at the dispensary stations alone forms a serious item of expense. The dispensary doctor has himself to pay the travelling expenses which he must necessarily incur in discharging his public duty. This anomaly is the more grievous and unjust because these expenses, which ought to be a public charge, are paid for out of a salary that does not afford even the necessaries of life. It should be strongly urged on the Local Government Board that the want of allowance for the cost of travelling on dispensary duty in rural districts is a grievous injustice to the sick poor as well as to the doctor.

Registration, vaccination, and sanitation are extras, but are very poorly paid and oftentimes car-hire eats up the remuneration. With regard to holidays the report speaks very strongly :—

> There is no service in these countries where the duties of the officers are so laborious and so unceasing as in the Irish dispensary service. There is none so poorly paid. The work of a dispensary doctor is always responsible; it is often laborious even to drudgery; at times it is full of danger to health and life and, worst of all, it is incessant. Anyone of these conditions would entitle him to some period of certain rest and change. But when all these conditions are combined an annual holiday becomes absolutely imperative. "Nature must obey necessity." The dispensary doctor must be prepared for official duty every hour of the day and of the night, on Sundays as on week-days, on holidays as on other days, all the year round. There is no parallel for such a constant strain of continuous duty. The Local Government Board should exercise their power under Secs. 8 and 12 of 14 and 15 Vic. Cap. 68, to secure for all Poor-law medical officers a fixed annual holiday, with paid substitute, as an absolute necessity for the efficient performance of their duty.

The report points out that Civil Servants get six weeks' holiday, and we might add that even bank clerks get a month. A holiday for hard-working people is an essential.

The report goes on to cite cases of nine dispensary medical officers dying at an average age of thirty-seven years. It then considers the case of old men of even ninety years of age dying in harness because the committees would not grant them a pension. The report makes many recommendations, all of which advocate the Local Government Board as the beneficent power. This, we take it, will not make the recommendations of the Association popular with the various dispensary committees.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

The forty-fourth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Jan. 17th. The Commissioners present were Lord Llandaff (the chairman), the Right Hon. J. W. Mellor, Sir John Dorington, Sir George Barclay Bruce, Mr. de Bock Porter, Mr. Robert Lewis, and Major-General Scott. The witnesses examined were Sir William Crookes and Mr. James Dewar, who are employed by some of the metropolitan water companies, and Sir Edward Frankland, K.C.B., the water analyst to the Local Government Board.

At the commencement of the proceedings Mr. Pember, Q.C., gave a disquisition on the bearing and consequences of the legislation of 1852 and 1871 with regard to the constant supply of water to the metropolitan area and in the course of his remarks he quoted freely from the sections of those Acts which related to the subject.

Sir William Crookes, in reply to the Chairman, said that he had been concerned in the systematic chemical examination of London water since the year 1881. He was paid by some of the metropolitan water companies but he regarded himself as acting in the interests of the water consumers. The witness put in some diagrams.

The Chairman, referring to one of the diagrams, asked the witness whether he wished them "to draw the inference that the best thing is to draw Thames water when it is in flood so as to get only a few microbes."

Mr. Mellor said, "That is what this plan would show," and the witness said, "All the results of our experience show that." In answer to a further question from Sir G. Bruce as to whether there were fewer microbes in flood-water the witness replied that there were.

In answer to Sir George Bruce the witness said that the rain washed down a certain quantity of microbes from the land, but that the amount of impurity which the rain brought into the river was little in comparison with the enormous dilution it produced.

Mr. Pember, referring to the fact that the diagram showed that the number of microbes increased as the flow over Teddington Weir became smaller, suggested that this was due to the greater vitalising power of the sunshine over shallow water and to the generative power of the sun. The witness, however, said that sunlight had a deleterious effect upon microbes.

Sir George Bruce said that the number of microbes was in inverse proportion to the amount of water. Later in his examination the witness said that when there was a small flow over Teddington Weir there were very few microbes.

In answer to Major-General Scott the witness said that the only advantage of allowing water to subside in a reservoir was that the deposit which took place would save the filters, for the filters would become foul more rapidly with turbid water than with clear water and if turbid water were put straight on the filters a larger number of filters would be required to give the same result. The witness admitted that it was not desirable if it could be avoided to take water out of the river in a turbid condition and to put it directly on the filter beds. He was not aware that in the scheme for the Staines reservoirs as a general rule the water was to be taken out of the river and put directly on to the filters.

Major-General Scott pointed out that this was the fact and asked whether there ought not to be some limit to the character of the water which was taken and sent down to the filters, and whether it would not affect the quality of the filtered water, taking into account the fact that filters would more rapidly become foul when turbid water was used. The witness replied that there were rules and a proper amount of supervision was exercised over the water companies and that the rate of filtration was already regulated by Act of Parliament and was 2½ gallons per square foot per hour.

Major-General Scott pointed out that no such statutory regulation as the witness suggested was in force. The witness said that he thought there was such a statutory obligation.

In answer to Major-General Scott the witness said that any quantity of water could be dealt with if there were a sufficient number of filters. He would not admit, however, that if flood water were taken the number of filters necessary would be so enormous that it would be a most uneconomical thing to use water straight from the river.

In answer to the Chairman the witness said that he did not think that any restriction in taking flood water was necessary, but he admitted that in Thames water there were more microbes in flood than when the river was not in flood.

In answer to Sir George Bruce the witness said that during the period of flood there were more microbes per cubic centimetre.

In answer to the Chairman the witness said that it did not matter if there were three or four hundred microbes per cubic centimetre if they were harmless ones. He thought that the whole question of microbes was more a sentimental than a practical question.

Sir George Bruce asked the witness whether unfiltered Thames water could be drunk without doing any harm. The witness replied: "I do not think one would take harm," and he added that he would not object to drink it himself.

Mr. James Dewar, in answer to the Chairman, said that the number of microbes per cubic centimetre in Thames water was increased during times of flood. After every shower of rain in river water there was always a large increase in the number of microbes present. The amount of microbes in the filtered water depended entirely upon the efficiency of filtration.

In answer to Sir John Dorington the witness said that there was no relation between the condition of the river and the bacteriological condition of filtered water.

The Chairman remarked that in that case the diagram which had been shown to them was wholly misleading. The witness would not agree with this criticism and said that in every case the number of microbes present depended on the condition of the filters.

The CHAIRMAN insisted that in so far as the diagram which had been shown to them conveyed any results it conveyed misleading results

Major General SCOTT asked whether there was not this general coincidence—that water containing a greater amount of sediment would contain a greater amount of bacteria, and that if flood water contained a greater number of bacteria than water which was not flood water and flood water contained a greater amount of sediment than water which was not flood water, did it not follow that water which contained a great number of bacteria would generally contain a large amount of sediment? The witness replied that that was not so

Major General SCOTT asked the witness to explain The witness replied that suspended matter was not necessarily objectionable but that, on the contrary, it was advantageous in getting rid of bacteria Suspended matter did good *The settlement of water containing solid matter in suspension was as effective in getting rid of bacteria as filtration*

Major General SCOTT said that that was not the point on which he wished for information, but he wanted to know whether when the Thames was in flood it deposited a considerable amount of sediment, and the witness admitted that this was the case

Major General SCOTT asked if the Thames when in flood did not contain a considerable amount of bacteria, and the witness replied that that was so

Major General SCOTT then asked whether it was not a fact that when the river contained a considerable amount of sediment it also generally contained a considerable number of bacteria The witness then admitted that the facts were as Major General Scott had suggested

Major General SCOTT asked if in the case of water containing a large amount of sediment the filters would not become more quickly choked The witness admitted that this was so, but he would not admit that it therefore followed that if such water was *taken a larger filtration area* would be necessary He admitted, however, that filters would have to be more frequently washed and Major General SCOTT pointed out that whilst the filters were being cleansed they could not be used

In answer to the CHAIRMAN the witness said that under the present system of filtration the number of microbes was generally reduced by the metropolitan companies to less than 100 bacteria per cubic centimetre

The CHAIRMAN asked if there were 20 000 whether they would do any harm The witness replied that it would depend upon their character He had never found any morbific bacteria in the water

The CHAIRMAN asked why if the bacteria were not harmful it mattered if there were 100 or 200 per cubic centimetre and suggested that from the witness's evidence it appeared that all this fuss about bacteria was mere idle talk

Sir EDWARD FRANKLAND, K C B, said that the Local Government Board had very little legal power over the metropolitan water companies and that so far as he knew the Local Government Board had never attempted to place any restraint upon the companies with regard to the taking of water during flood, they had, indeed, no legal right to do so

In answer to Major General SCOTT the witness said that there was no doubt that storage enormously decreased the number of microbes—there was no doubt whatever upon that point

The CHAIRMAN asked whether the character of these microbes was fully established, whether *innocent* microbes might become mischievous, whether they might "go mad as it were" The witness replied that microbes were not subject to such changes The witness said that he thought that every metropolitan company ought to have a sufficient storage capacity for thirty days supply,

In answer to the CHAIRMAN the witness said that he found that as a rule when the Thames was highly charged with microbes the number of them in the filtered water supplied by the companies was larger than it was when the Thames water was *purer and freer from microbes*

The CHAIRMAN handed to the witness the diagram which had been put in by Sir William Crookes and said that it had conveyed to his mind the impression that the average number of microbes in filtered water varied in inverse ratio to the height of the river The witness said that that observation was not in accordance with the results which he had obtained

In answer to Major General SCOTT the witness said that as a rule he had found that the number of microbes was greater in flood water than it was when the river was running at the ordinary level, and he stated that as a general fact in a filtrate of flood water there were more microbes as a rule than there were in a filtrate of water that was not flood water

---

The forty fifth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Jan 23rd The Commissioners present were the Chairman (Lord Llandaff), Sir John Dorington, Mr de Bock Porter Mr Robert Lewis, Mr Cripps, Q C, and Major General Scott

At the commencement of the sitting Mr BALFOUR BROWNE on behalf of the London County Council said that that body would be willing that the witnesses who had appeared before the Commission should assist Colonel Rathborne in the inquiry which he was undertaking and that Sir Alexander Binnie had already been in communication with the new Assistant Commissioner

Mr CHARLES EDWARD GROVES, F R S, the chemist employed by the Thames Conservancy, gave evidence with regard to the chemical condition of the Thames water He gave it as his opinion that flood water could quite safely be taken by the metropolitan water companies from the first hour of flood and during the whole period of flood.

The witness said that there had been a great improvement in the water of the Thames since the Thames Conservancy Act of 1894 had been put into force Since that date the amount of pollution had been diminished to the extent of about two thirds Pollution resulted from the effluents from the sewage farms which entered the river, and if the entrance of sewage effluents could be entirely prevented greater purity would necessarily be secured

In answer to the CHAIRMAN the witness said that when turbid water was allowed to settle slowly the solid matter carried down a great quantity of the organic matter which was present in the water *He thought the fear that the* Thames was excessively polluted by organic matter during periods of flood was groundless In his experience a comparatively slight flood after excessive and continued drought raised the amount of organic matter present by less than one half. When the river was in high flood and overflowed the banks the water became very turbid, but the amount of organic matter suspended and dissolved in it did not become very great and the excess could be removed by storage and filtration The purification of sewage ought always to be effected by passing it over land, because *in that way* pathogenic organisms were destroyed

In answer to Mr BALFOUR BROWNE the witness said that he was not aware that Dr Klein had proved the presence of pathogenic organisms in water supplied to Londoners

Mr HENRY CARRINGTON BOWLES, Governor of the New River Company, in answer to the Chairman said that prior to the year 1852 the company had sold their water to their customers at a charge arranged in each case by agreement The company were under no restriction as to the charges which they were entitled to levy nor were they obliged to give a supply of water Under the terms of the New River Act of 1852 the company were compelled to give a supply at a statutory scale of charges but there was no statutory limit as to the amount of profits which the company might divide. It was the wish of the company to have the most friendly relations with their customers As a matter of fact the company did not charge their customers the full statutory price In the case of the City of London the *charges* were roughly speaking, two thirds only of the amount which they had a right to receive If the undertaking of the New River Company were bought by the London County Council it would be injurious to the City of London

The CHAIRMAN asked the witness why they did not "bleed the City properly" It was suggested that they might charge as much as they were entitled to in the City and make large reductions to their poorer customers in less prosperous parts of the metropolis The witness said that he had no doubt that in the future as in the past the company would be able to perform to the utmost their obligations to the public They had always been prepared for any possible increase in the consumption of water and their policy had been to provide for it in advance *With their* existing arrangements and with those which they had in contemplation provision had already been made which would enable them to have a sufficient supply of water to carry them on his opinion there was ample control over the affairs of the company. Their accounts were examined by the auditor appointed by the Local Government Board; the filtration of their water was watched and reported on by the water examiner to the Local Government Board, and he would have no objection whatever to the water examiner having a statutory right to enter their premises at all times. The witness said that in his opinion the undertakings of the metropolitan water companies were too great to be under one management unless a separate Government department were formed for that purpose.

The CHAIRMAN remarked that Government departments were not always considered to be models of efficient supervision.

The forty-sixth meeting of the Royal Commissioners was held at the Guildhall, Westminster, on Jan. 24th, when the examination of Mr. Bowles was completed and Mr. Searle, the secretary, and Mr. Francis, the engineer to the New River Company, were examined by the Commissioners. The latter was cross-examined at some length by Lord Robert Cecil on behalf of the Hertfordshire County Council.

THE INFLUENCE OF SCHOOLS IN ACCENTUATING THE SPREAD OF CERTAIN INFECTIOUS DISEASES.

II.

IN our last article in THE LANCET of Jan. 21st we briefly traced the growth of knowledge as to the influence of schools in connexion with the diffusion of infectious disease, and we drew attention to the valuable and instructive investigations of Mr. Shirley Murphy with regard to the elementary schools of the metropolis. If, however, schools have had a marked effect in accentuating the incidence of diphtheria and other infectious diseases on certain age groups in London, it is only reasonable to expect that a somewhat similar influence should, if carefully looked for, be detectable elsewhere. But at the threshold of an inquiry into this aspect of the question we are met with the difficulty that in but few places has such care been exercised to discover the facts as has been taken by Mr. Murphy in connexion with the London figures; indeed, some investigators have by a somewhat imperfect conception of the real issues at stake needlessly complicated matters.

If, however, the mortality figures for England and Wales, excluding London, are studied as a whole it is found that they manifest similar changes to those for London taken either alone or in conjunction with those for England and Wales, and as Mr. Murphy points out in the report[1] with which we are now mainly dealing, there has been in each of the populations above referred to a notable increase of relative incidences of diphtheria mortality since 1861–70 upon children at school age, and "so far as the figures antecedent to the period 1861–70 may be trusted, there is observable difference in the behaviour of the figures in the period before and after that period." Mr. Murphy discusses the several factors which may be considered to have had to do with this altered age incidence, such, for instance, as altered nomenclature, natural variations, and varying social conditions of the community, and after fully dealing with each of these questions he arrives at the conclusion that the aggregation of children in schools is the best explanation of the phenomena observed.

When, too, the available notification figures for certain large towns other than London are separately examined as regards diphtheria incidences on age groups Mr. Murphy finds, contrary to the conclusions arrived at by Dr. W. R. Smith, the medical officer of the London School Board, who it appears examined only the "all ages" figures for some of these towns, that there are distinct indications of a fall in the number of notifications during the summer holiday period in the case of Bradford, Birmingham, Nottingham, West Ham, Salford, Sheffield, Bristol, and Manchester. These results have been brought out by grouping the cases in respect to age for three equal period i.e., before holiday influence, during holiday influence, a subsequently to holiday influence. So, too, in reference to figures for Berlin, Mr. Murphy, without of course attachi any great importance to "all ages" figures, shows nev theless that there are even here indications of sch influence; and this in spite of the fact that Dr. Smith, w had regard to the deaths alone, failed to detect any su influence.

There is, however, another side from which this qu tion of school influence may be approached, and th is by a consideration of the operations of each separ school in any given district. It is perfectly obvious to epidemiologist that all schools are not always operating the diffusion of infectious disease, and it is probable that times no school in a given locality may be thus operati This being so the influence for harm of any given schoo schools may be swamped as it were by the negative influe of many other schools. Dr. Niven, the medical officer health of Manchester, has been at pains to consider scarlet fever incidence in relation to each school in district, and in his last annual report he shows very clea how while the majority of schools were, during the per to which the inquiries related, not potent for mischief, oth were very materially so; and his study shows further necessity of approaching the operations of any given sch by a separate examination of each of the departments that school. As Dr. Niven observes at the conclusion of investigations, "the statistics given by Mr. Shirley Murp are clearly supported by this inquiry as to fact and sig ficance."

We do not propose to further discuss the manner in whi Dr. W. R. Smith's arguments are dealt with by Mr. Murp in his report now before us, inasmuch as we noticed Smith's report at some length in our columns at the time its publication in 1896.[2] It seemed to us then, and it see to us still, that much of that report was not altoget relevant to the issue. For instance, Dr. Smith discussed incidence on several counties or groups of counties in Engla and, in consequence of the unequal and varying incidence the disease on the several areas, he was apparently towards his conclusion that schools exercised but an important influence in the spread of diphtheria. For part we have never been able to see the force of this arg ment, and it would seem to us to be equally illogical to in that because the incidence of enteric fever varies ve materially in different counties and parts of England, a that it may at times be difficult to determine the [illegible] thi specifically contaminated water may have had in the spre of the disease that therefore the influence which co taminated water has had in the country as a whole "unimportant" and no very special measures have be needed to check its operations.

The bacillus of enteric fever is, as far as we can ascert or infer, not always present in our public water-suppli and even when it is present it but rarely finds itself und conditions prone to its multiplication. Similarly with resp to diphtheria the bacillus of that disease is not always pres in all our elementary schools and when it *does* obtain en therein the conditions necessary for promoting a high deg of infectivity are doubtless often absent.

In our view, however, the question of polluted wat supplies and of the spread of infectious disease by means elementary schools both need vigorously dealing with, a in our next article we shall discuss the improvements this direction of school regulations.

HUNTER *v.* CLARE.

IN the Queen's Bench Division of the Royal Cou of Justice on Jan. 24th this case was heard before Justice Lawrance and Mr. Justice Channell. Mr. H dane, Q.C., and Mr. Condy appeared for the appellant Mr. Muir Mackenzie for the respondent. The real parties the dispute were the Society of Apothecaries on the hand and the General Medical Council on the other. question at issue was whether a Licentiate of the Soci of Apothecaries was entitled to describe himself as physician. The present case was one stated by

---

[1] London County Council Paper: Report by the Medical Officer of Health on Diphtheria and Elementary Schools. No. 399. Price 1*s.*; post free 1*s.* 1½*d.* P. S. King and Son, 9, Bridge-street, Westminster, S.W.

[2] THE LANCET May 23rd, 1896, and June 13th, 1896.

Justices of Cambridge who fined the late Mr. Kingsley Hunter, L.S.A., £5 and 3 guineas costs under Section 40 of the Medical Act of 1858 for "wilfully and falsely pretending to be and taking and using the name and title of physician." The application for the decision of the Queen's Bench Justices was argued at length occupying the whole of the morning sitting of the Court. After lunch the following judgments were delivered:—

Mr. Justice Lawrance said that the real question the court was asked to decide was whether a person having the certificate of the Society of Apothecaries, by virtue of which he is entitled to work both at medicine and surgery as well as an apothecary, is entitled to describe himself as a physician or whether in so doing he contravenes Section 40 of the Medical Act, 1858. In his lordship's judgment such a person was not entitled to describe himself as a physician and if he did so falsely and wilfully the conviction was justifiable. Until 1886 the certificate granted by the Society of Apothecaries gave a qualification to practise as an apothecary only. In that year it was determined that for the future no one should be licensed to practise in any one of the three branches into which the profession is divided unless he had passed qualifying examinations in all. The appellant, whose diploma dated from later than 1886, called himself a "physician." How was that expression used? Was it a mere description of himself as a doctor in the colloquial sense or was it used to imply that he held a medical degree of a university or some qualification entitling him to act as a physician? To any ordinary mind the latter was what the word physician would imply. His lordship came to the conclusion that although there had been misdescription it was not wilfully false and that the conviction must therefore be quashed, but without costs, as the respondent had succeeded upon the main point.

Mr. Justice Channell said that upon the whole he was of the same opinion. He thought, though he was not without doubt, that the appellant had falsely described himself as a physician. Whether that was so or not was the main question upon which the opinion of the Court was desired, for counsel, though nominally appearing for the appellant and respondent, had stated that they were really instructed by the General Medical Council and the Apothecaries' Society who wanted the point settled. The question was whether it is a true description for a Licentiate of the Society of Apothecaries to describe himself as a physician. That depended upon the sense in which the word "physician" was used in Section 40 of the Medical Act, 1858. *If in that section the word meant merely a person duly qualified to practise in physic then the appellant was a physician, because, though it was not so at one time, a Licentiate of the Society of Apothecaries now becomes entitled to practise medicine and surgery. But before the Act of 1858* physician was commonly used as applying to persons in the highest grade of medical practitioners and his lordship thought it was so used in the Act. There was confirmation of that interpretation in several places in the Act. In that sense a Licentiate of the Society of Apothecaries was not, in his opinion, a physician. His lordship then expressed his concurrence with Mr. Justice Lawrance in holding that the appellant had not wilfully misdescribed his qualification and that the conviction must therefore be quashed, though under the circumstances without costs.

THE WORSHIPFUL COMPANY OF PLUMBERS.

The annual dinner of the Plumbers' Company "to meet the Lord Mayor and the Sheriffs of the City of London" was held at Salters' Hall on Wednesday, Jan. 18th, under the presidency of the Master of the Company (Alderman Richard Hind). Amongst the large number of guests present were the Lord Mayors of Leeds, Sheffield, and Belfast, and Mayors of other important provincial towns and many well-known medical officers of health and others interested in sanitation. In responding to the toast of "The Houses of Parliament" Mr. T. W. Russell, M.P., Parliamentary Secretary to the Local Government Board, referred to the Plumbers Registration Bill and said that his department never had two opinions with regard to that Bill as the registration and examination of plumbers seemed to be so necessary and useful. His department had not changed its mind though it could not be said that the Bill was ideally drawn. The Bill had been under discussion for several years past and it had passed the second reading three or four times, but it seemed to him that many who pretended to be interested in the movement only came forward to support it when it reached the report stage. In conclusion, he expressed a sincere hope that the next time the Bill was introduced it would pass the House of Commons. The toast of "The Worshipful Company of Plumbers" was acknowledged by the Master who expressed a hope that the Houses of Parliament would soon confer upon the Plumbers' Company the authority which it wished to possess in the interests of the public health.

It may not on this occasion be out of place to remind our readers that The Lancet owes a debt of gratitude to the Worshipful Company of Plumbers. Some three or four years ago we appointed Special Commissioners to investigate the difficult subject of the "Relative Efficiency and Cost of Plumbers' Work." It occurred to us that if when our work was finished we could be so fortunate as to obtain an authoritative criticism, or at any rate a statement of opinion thereon, from such a high and competent authority as the Company of Plumbers, where the results of our Commissioners' labours were found to be of value that value would be enhanced by the approval of the Company; where they were considered to be faulty our readers would have the benefit of the Company's criticism. In answer to our application to the Company we received a courteous and kind reply acceding to our request, one stipulation only being made, and that a highly proper one—namely, that the "Report of of the Special Committee appointed by the Worshipful Company of Plumbers to offer criticism and suggestions upon the report of an inquiry undertaken by The Lancet into the subject of the 'Relative Efficiency and Cost of Plumbers' Work'" should appear as the work of a Special Committee appointed by the Company for the purpose and not as the work of the Company. The reason for this request was that the Company does not in its corporate capacity take any part in what may be regarded as "trade matters," but directs its efforts entirely to promoting the sound technical instruction of plumbers combined with the necessary arrangements for establishing an adequate system of registration and control over those men who are registered as qualified plumbers.

The Special Committee appointed by the Company went very thoroughly into the vast amount of detail which was contained in our report and must have devoted a very great deal of time and labour to the work. Their report was duly sent to us and published with that of our Special Commission in The Lancet of July 4th, 1896. The criticisms of the Special Committee were on the whole of a favourable nature and to their conclusions and findings of fact they added some valuable observations and suggestions.

We are glad to take this opportunity of tendering to the Worshipful Company of Plumbers in general and to the Special Committee in particular our cordial thanks for their coöperation—a coöperation which is probably unique, for never before surely have a City Company and a medical journal joined hands in the cause of sanitary science.

Several of the City Companies are becoming very useful allies in the cause of public health. The Plumbers' Company, although in their corporate capacity they do not take any part in what may be regarded as trade matters, yet exercise great influence over that branch of commerce which is represented by plumbing, and do all they can to promote the sound technical instruction of plumbers and by some useful form of control such as registration to protect the public from the too common dangers of defective plumbing work. The Grocers' Company afford another instance in the splendid support which they give by their scholarships to scientific research, and other City Companies by their liberal donations to hospital funds and hospitals evince their interest, if not in public health, in the health of the public. Of the fact that the City of London itself recognises the work of, and wishes to honour, those whose life duty it is to guard the health of the public a remarkable illustration was afforded when in May last the Lord Mayor of London invited representative members of the medical profession to dine with him at the Mansion House—the City thus publicly honouring Medicine. We have no hesitation in saying that that honour was appreciated by the medical profession throughout the country.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.

The Secretary of State for the Home Department has made the following further appointments of medical referees under the Workmen's Compensation Act, 1897:—

England.

Circuit No. 21.—Dr. Thomas W. Thursfield, Leamington.

Circuit No. 25.—Mr. Alfred Owen Davies, Machynlleth, and Mr. Horace Allan Debenham, Presteign.

Circuit No. 53.—Dr. [illegible] Evans, Lowestoft, in lieu of Mr. C. H. Graham, resigned.

Circuit No. [illegible]—Mr. Robert Bruce, Milford-on-Sea.

Ireland.

County Louth.—Dr. Thomas Joseph Moore, [illegible]

County Londonderry.—Dr. Benjamin [illegible] Browne, resigned.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6875 births and 3979 deaths were registered during the week ending Jan. 21st. The annual rate of mortality in these towns, which had been 19·1 and 18·3 per 1000 in the two preceding weeks, further declined last week to 18·2. In London the rate was 17·2 per 1000, while it averaged 18·8 in the thirty-two provincial towns. The lowest death-rates in these towns were 13·7 in Derby, 13·8 in Burnley, 14·4 in Leicester, and 15·1 in Croydon; the highest rates were 22·4 in Halifax, 22·6 in Preston, 23·0 in Gateshead, and 26·6 in Swansea. The 3979 deaths in these towns included 380 which were referred to the principal zymotic diseases, against 368 and 352 in the two preceding weeks; of these, 104 resulted from whooping-cough, 98 from measles, 68 from diphtheria, 46 from "fever" (principally enteric), 32 from scarlet fever, and 32 from diarrhœa. The lowest death-rates from these diseases were recorded in Oldham, Croydon, Halifax, and Wolverhampton, and the highest rates in West Ham, Preston, Huddersfield, and Nottingham. The greatest mortality from measles occurred in West Ham, Manchester, Huddersfield, Nottingham, and Gateshead; from whooping-cough in Cardiff, Bristol, Swansea, Huddersfield, Nottingham, and Birkenhead; and from "fever" in Bolton, Preston, and Burnley. The mortality from scarlet-fever showed no marked excess in any of the large towns. The 68 deaths from diphtheria included 30 in London, 5 in Liverpool, 4 each in West Ham, Portsmouth, Leicester, and Sheffield, and 3 each in Birmingham and Leeds. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and only 1 small-pox patient was under treatment in the Metropolitan Asylum Hospitals on Saturday last, Jan. 21st. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on the same date was 2749, against 2939, 2912, and 2777 at the end of the three preceding weeks; 249 new cases were admitted during the week, against 225, 291, and 220 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 365 and 363 in the two preceding weeks, further fell to 295 last week, and were as many as 412 below the average. The causes of 61, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Bolton, Oldham, Sheffield, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 18·2 to 21·7 per 1000, declined again to 21·3 during the week ending Jan. 21st, but exceeded by 3·1 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·5 in Leith and 17·1 in Greenock to 22·4 in Glasgow and 23·5 in Dundee. The 649 deaths in these towns included 34 which were referred to whooping-cough, 20 to diarrhœa, 19 to measles, 9 to diphtheria, 6 to scarlet fever, and 6 to "fever." In all, 94 deaths resulted from these principal zymotic diseases, against 78 and 88 in the two preceding weeks. These 94 deaths were equal to an annual rate of 3·1 per 1000, which was 1·4 above the mean rate last week from the same diseases in the *thirty-three large English towns.* The fatal cases of whooping-cough, which had increased from 14 to 35 in the three
precedingthe mks, were 34 last week, of which 15 occurred
"who it appeai in Edinburgh, and 3 in Dundee. The
for some of theseasles showed a further increase upon those

S.W.

organs in these towns, which had been 123 and 156 in the two preceding weeks, were 153 last week, and exceeded by 14 the number in the corresponding period of last year. The causes of 30, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·7 and 27·1 per 1000 in the two preceding weeks, further rose to 28·6 during the week ending Jan. 21st. During the past four weeks the rate of mortality in the city has averaged 27·5 per 1000, the rate during the same period being 18·2 in London and 22·8 in Edinburgh. The 192 deaths registered in Dublin during the week under notice showed an increase of 10 upon the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 13 and 10 in the two preceding weeks; of these, 4 resulted from whooping-cough, 3 from "fever," 1 from diphtheria, 1 from scarlet fever, and 1 from diarrhœa, but not one either from measles or small-pox. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 1·5 in London and 4·0 in Edinburgh. The fatal cases of whooping-cough, which had been 6 and 3 in the two preceding weeks, rose again to 4 last week. The deaths referred to different forms of "fever," which had been 4 and 1 in the two preceding weeks, rose again to 3 last week. The mortality from scarlet fever corresponded with that accorded in the preceding week, while that from diphtheria showed a decline. The 192 deaths in Dublin last week included 34 of infants under one year of age and 54 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Ten inquest cases and 6 deaths from violence were registered; and 76, or more than a third, of the deaths occurred in public institutions. The causes of 12, or more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

STAFF SURGEON JOHN BELLHOUSE BOWDEN TRIGGS has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

The following appointment is announced:—Surgeon R. Waterfield to the *Diadem.*

ROYAL ARMY MEDICAL CORPS.

Lieutenant George S. Nickerson is seconded *for service* with the Egyptian Army. *Lieutenant* A. C. Lupton is appointed to the Coldstream Guards as an attached Medical Officer. Captain J. Thomson has embarked for India. Lieutenant H. O. B. Browne-Mason embarks *for service* in India. Brigade-Surgeon H. Harrison, r.p., late A.M.S., is appointed to the Medical Charge of the 49th Regimental District as a retired officer.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Captain Hogg, 8th Bengal Cavalry, are placed temporarily at the disposal of the Chief Commissioner of the Central Provinces for employment on plague duty.
Surgeon-General R. Harvey, *C.B.*, D.S.O. (Bengal), is con-
firmed in the appointment of Director-General, Indian
Medical Service, and Sanitary Commissioner with the
Government of India, from Oct. 25th, 1898. Lieutenant-
Colonel A. J. Wilcocks, Civil Surgeon in medical charge
of the Camp of His Honour the Lieutenant-Governor and
Chief Commissioner, is granted furlough, partly in and
partly out of India, for two years, with effect from Jan. 1st,
1899.

VOLUNTEER CORPS.

Rifle: 4th Volunteer Battalion the Queen's (Royal West
Surrey Regiment): Surgeon-Lieutenant E. J. G. Berkley to
be Surgeon-Captain. 4th Volunteer Battalion the East
Surrey Regiment: Charles James Martin to be Surgeon-
Lieutenant. 1st (City of Dundee) Volunteer Battalion the
Black Watch (Royal Highlanders): Surgeon-Lieutenant
J. S. Y. Rogers to be Surgeon-Captain. 13th Middlesex
(Queen's Westminster): Surgeon-Captain A. J. McD. Bentley
resigns his commission.

THE UNITED STATES ARMY AND THE LATE WAR.

Our service contemporary, the *Army and Navy Gazette*, of Jan. 21st in a long article under this heading, reviews the military reports which have been recently published by the Commander-in-Chief, Surgeon-General Sternberg, and General Merritt of the United States Army. The information contained in these reports will be read with much interest, and the lesson to be deduced from the facts being one of wide application and of practical importance we may briefly refer to them. In the first place it was recognised from the beginning, as we always contended would have to be the case, that if the Spanish position in Cuba was to be successfully attacked the United States navy must be mainly relied upon to do the work. As far as her army was concerned America was quite unprepared. Two very serious obstacles had to be avoided—viz., the disembarkation, on the one hand, of any land force in Cuba before the navy had secured complete command of the Cuban waters; and, on the other, the landing of any large military force on the island during the rainy or sickly season, which would, however, give an opportunity for carrying out the necessary naval operations, whilst at the same time admitting of the mobilisation, organisation, training, and equipment of the volunteer army. The advice tendered to the United States Government by their military authorities on these rudimentary points leaves little or nothing to be desired, for it appears to have been very wise and sound. But these very necessary preliminary arrangements were not, or could not be, fulfilled. It was a most fortunate circumstance for the American Government that the opposition, as far as the Spanish navy and army were concerned, proved to be so bad and weak as it turned out to be. As regards the medical history and aspects of the war, with which we are mainly concerned, the report of the Surgeon-General affords a very plain and sufficient explanation of the breakdown of the medical arrangements and of the amount of sickness, suffering, and mortality which followed. The medical staff of the United States army when the war broke out only amounted to 192—an utterly inadequate provision. This rendered a hurried call for the services of a supplementary staff of 650 "contract surgeons" necessary. Now it is no reflection upon the professional merits of these surgeons to say that they were foredoomed to failure. It is simply impossible for the most able and energetic practitioners drawn from civil life but totally ignorant of military methods of procedure to know what is absolutely essential for the elementary requirements of field medical service in the way of army organisation, administration, and hygiene. The great prevalence of avoidable sickness in the various camps was not so much due to the sites for such camps being badly chosen as to the imperfect sanitation that was maintained and the want of training on the part of those who had suddenly to encounter conditions of which they had no previous knowledge and experience. The trained hospital nursing corps, moreover, was quite insufficient; there was, it is alleged, an abundance of medical supplies but it was impossible to find adequate or timely transport for them, so that they might just as well have been a thousand miles away, for not being forthcoming when required it was a case of starvation amidst plenty. Lastly, although this does not exhaust all the factors that might be enumerated, the age limit for recruits had been reduced from twenty-one to eighteen, which is stated to have been found "a fatal misjudgment." The inefficiency from sickness among very young troops on taking the field is always large, especially in such a climate as Cuba It is only right to say that General Merritt's report of the operations in the Philippines, where the difficulties which had to be encountered were much less than in Cuba, is of a much more satisfactory character. There was an abundance of hospital supplies of all kinds, the accommodation provided for the sick and wounded was good and sufficient, and there were, practically speaking, no grounds for complaint.

THE GRENADIER GUARDS AND RIFLE BRIGADE AT KHARTOUM.

Mr. Steevens in his graphically written book, "With Kitchener to Khartum," was, it seems, labouring under a serious misapprehension (which he has since acknowledged and corrected) when he said that the Grenadier Guards and Rifle Brigade had a bad reputation for going sick and sent more men into hospital in a week than the whole of the 1st Brigade. We know now that, according to the official returns, and on the authority of the officer commanding the 2nd British Brigade of the Khartoum Expeditionary Force, such was not the case. As a matter of fact, the Guards, with the exception of the Cameron Highlanders, were the healthiest of the eight battalions in the British Division, and were in all respects a highly efficient corps. As regards the Rifle Brigade, however, there was a good deal of ineffectiveness from fever owing to a large number of the soldiers of that corps having previously served in China and at Singapore and to their subsequent hard work and exposure in the Soudan; but on the day of the battle at Omdurman they turned out, Brigadier-General Lyttelton states, only slightly weaker in strength than the other battalions.

THE BRITISH TROOPS IN CRETE.

Major-General Sir H. C. Chermside, commanding the British troops in Crete, in his despatch concerning the gallant behaviour of the Highland Light Infantry and men of other corps in Candia on the occasion of the difficult and dangerous crisis that occurred in the treacherous attack on the British garrison on Sept. 5th, 1898, includes in the list of names recommended for favourable consideration the following: Royal Army Medical Corps; Lieutenant L. Addams Williams, Lieutenant T. H. M. Clarke (wounded), Private D. Philemon, Private G. H. Lowden, Private G. Leggatt, and Private G. Biddiscombe (wounded).

ARMY MEDICAL SCHOOL, NETLEY.

The seventy-seventh session of the Army Medical School will be brought to a termination on Tuesday, Jan. 31st, when the prizes gained will be distributed by Sir Ralph Knox, K.C.B., Permanent Under Secretary of State for War.

DEATHS IN THE SERVICES.

Fleet Surgeon Godfrey Goodman, R.N. (retired), on the 20th inst., at his residence, Cullompton, Devon.

Correspondence.

"Audi alteram partem."

"THE NEW MIDWIVES BILL."

To the Editors of THE LANCET.

SIRS,—Dr. Alexander McCook Weir calls attention in THE LANCET of last week to your editorial remark in November last that "No Midwives Bill which we have yet seen contains any provision for ensuring that in every case a lying-in woman, however poor, shall have the benefit of qualified medical attendance, and without such provision no Midwives Bill should pass." He goes on to show that in a Bill drawn by him called "A Sick and Obstetric Nurses Bill" there was a clause making it unlawful for any person (male or female) to assume the title of midwife or to practise as such, or to act as a sick and obstetric nurse for gain or otherwise without the supervision and control of a fully qualified and registered medical practitioner, any infringement of this rule to render the person infringing it liable to a fine of £10 or imprisonment for a month.

I wish to point out that in the report of the Committee of the General Medical Council on the Bill of 1898 amongst other *indispensable* requirements in any such measure the following provision was made:—

> That it shall be the *duty of the local sanitary authority of every* district to appoint such registered medical practitioners as are willing *to be so appointed* to whom midwives shall be required to apply for assistance and advice in all cases other than cases of natural labour and *under all circumstances* which may be laid down by the Midwives Board as calling for medical intervention. The local authority shall pay to every registered medical practitioner so consulted a sum of not less than one guinea and not more than two guineas, provided always that when the patient is able to pay for such medical services the local sanitary authority shall recover the fees for the same from the patient or other responsible person by ordinary process of law.

When the report came to be discussed in the General Medical Council this provision was modified as follows:—

> That the regulations under which licensed midwives are required to practise should include provisions securing that the midwife shall im

presents symptoms of difficulty, abnormality, danger, or disease on the part of the mother or of the new-born infant.

The principle of the two clauses is the same, but while that of the Committee provides for the insertion of the requirement with some details expressly in the Bill, that of the Council entrusts the matter to the Midwives Board to be provided for in their regulations, which are to be subject to the approval of the General Medical Council.

The difficulty of inserting any clause involving money payment in private Bills is probably the reason of the non-insertion of such a clause. But I think the omission is to be regretted. I recognise the effort of the promoters to comply with the general views of the General Medical Council and cannot doubt that they do not differ seriously from the Council in wishing to subordinate all midwives' work in cases of "difficulty or abnormality" to the supervision and control of medical practitioners—a *sine qua non*, in my judgment, of all legislation of this sort.

I am, Sirs, your obedient servant,
Highbury-place, Jan. 25th, 1899. JAMES GREY GLOVER.

"OLD AGE AND REJUVENESCENCE."

To the Editors of THE LANCET.

SIRS,—In considering whether it is possible to increase the racial span of life—i.e., the inborn tendency to longevity—we must not forget that it is very doubtful whether characters impressed upon the individual by the environment (= acquired characters) are inherited, and whether therefore the acts of the parent before the conception of the child greatly influence the latter's career. Be this as it may, it seems certain that evolution proceeds essentially by "selection," from which it follows that the most effective way of producing a long-lived race is by allowing only those to marry who belong to long-lived families. In this way the span of human life might be prolonged almost indefinitely. In another place I have given reasons for my belief that the tendency of every living thing is towards immortality, and that senility is brought about by means specially evolved for the purpose, because it is of advantage to a species that its members should not live beyond a certain term, this term differing for different species, so that the processes which make for senility come into operation at different periods for different races. While therefore I hold that the most effective way of evolving a long-lived race of men is by artificial selection, I believe the best way to prolong the life of any given individual, apart from ordinary hygienic means, is to be sought for in the study of those mechanisms by which senility is normally and physiologically induced.

What these mechanisms are cannot at present be stated very definitely. I believe, however, it will be found that changes in the composition of the blood, whether by modification in internal secretions or what not, play an important part in determining senility, and that Brown-Séquard's attempts at rejuvenescing the old were not altogether chimerical. It is certain, again, that the cardio-vascular system takes a large share in inducing senility; the degree of systemic arteriolar resistance helps to set the vital pace, an abnormally high resistance causing premature senility by prematurely wearing out the heart and arteries, and in this way influencing the entire bodily nutrition. If therefore we wish to keep a person young we should keep his blood-pressure low, and I believe that we can in this way stave off senility even more effectually than by the plan adopted by Dr. Althaus.

Dr. Ainslie Hollis seems to hint that delayed marriage tends to delay puberty in the offspring. I doubt whether this is the case. There is, indeed, a popular belief that the children of old men tend to develop prematurely. Such marriages probably do, however, tend to racial longevity. If, for instance (to take an extreme case), every man delayed marriage till forty, the large number of men who die before this age from disease would be prevented from leaving children inheriting a similar tendency to early death. In this connexion I would observe that the custom of monogamy operates injuriously as regards the extension of racial life. Under this system men are for the most part prevented from begetting children after fifty, and thus those who live to be very old do *not as a rule have more* children than those who die at middle age. Under a system of polygamy, however, the former would leave the more numerous progeny, and thus there would be a proportionate increase in the number of children born into the world with an inherited tendency to longevity. I am, Sirs, yours faithfully,
Wimpole-street, W., Jan. 22nd, 1899. HARRY CAMPBELL.

To the Editors of THE LANCET.

SIRS,—In your leading article on my paper on the above subject in THE LANCET of Jan. 21st you state that "he appears to us to forget that obviously the vital energy of the subject, his hereditary clockwork, must still be in fair working order." Allow me to say that I have by no means *forgotten this, as* shown by my remark that "I have come to the conclusion that if old people receive about the sixtieth or sixty-fifth year, *or indeed at any time when age has begun decidedly to tell upon them*, proper and faultlessly carried-out applications of electricity to the brain," then benefit may be expected. Of course, no one would think of applying electricity to an old person *in articulo mortis*, or in such a state of decrepitude that a response to any treatment appears to be unlikely. The treatment must be confined to elderly people who are, although decidedly failing, yet in tolerable condition and therefore likely to be benefited by it.

I am, Sirs, yours faithfully,
JULIUS ALTHAUS, M.D. Berlin.
Queen Anne-street, W., Jan. 21st, 1899.

*_** Dr. Althaus appears to mean that benefit is only to be expected from "faultlessly carried out applications of electricity" when the recuperative powers of the patient may be expected to exert themselves unaided or under other therapeutic measures. This is an intelligible view.—ED. L.

"IRRIGATION IN SUPPURATIVE OTITIS MEDIA."

To the Editors of THE LANCET.

SIRS,—Mr. F. Faulder White's letter on the above subject in THE LANCET of Jan. 21st and his criticism of Dr. Goldstein's views as expressed *in his article upon the* Therapy of Suppurative Otitis Media[1] does not seem to me to accurately place his (Dr. Goldstein's) views upon this important subject before your readers. Mr. White believes that the only efficient plan of cleansing the middle-ear cavity of its purulent contents is by means of warm irrigations, and adds, moreover, that such warm solutions are "invaluable in arousing the dormant vitality of the tissues." Dr. Goldstein, on the other hand, considers that the judicious use of the cotton-armed probe combined with inflation of the middle-ear by means of the Eustachian catheter and suction by means of a Siegle's speculum is sufficient to ensure cleansing of the part without increasing the already sodden condition of the mucosa, which, he says, is only accentuated by the addition of aqueous medication. Dr. Goldstein further remarks that he is referring only to cases of simple suppurative otitis media and not to cases of old-standing disease associated with necrosis and extensive destruction of the soft tissues of the middle-ear and possibly even involvement of the mastoid area. Mr. White, on the other hand, says that he refers to cases "of long standing in which there is no part of the middle-ear that can be said to be uninfected and yet open to the gentle force of an irrigating fluid, but there are certainly grave objections to the frequent use of the probe in the early stages of treatment."

For some considerable time past I have been in the habit of employing in early cases of suppurative otitis media—by which term I mean cases where the pathogenic infection is confined to the soft parts and where no bone lesion is present—the "dry method of treatment" and can claim not only good results but also more speedy recoveries than when solutions and irrigations have been made use of. It has always appeared to me that one of the main causes of the inveterate nature of certain middle-ear suppurations is due not to the virulence of the original pathogenic infection but to the engrafting of a secondary infection from without either from the use of unclean instruments, inefficient antiseptic precautions, or the generally surgically unclean habits of the patient. It has been held that the dry method of treatment should not be used in those cases where the perforation is small for fear of causing secondary retention of secretion, but I hold that no perforation should be allowed to remain in a condition which is judged to be inefficient to secure surgical drainage.

---

[1] The Laryngoscope, December 1898.

Such perforations should at once be enlarged by incision and as much fluid as possible removed from the middle ear by mopping, by inflation, and by suction with the pneumatic speculum. It is my custom then to pack the external meatus down to the edges of the perforation with thin strips of gauze—e g., double cyanide, iodoform, chinosol, &c.—and to subsequently place a pad of boric wool over the ear and fix it by means of a bandage or specially constructed silk ear cap. The dry gauze dressing appears in early cases to have a fourfold advantage: (1) in preventing the risks of infection from without; (2) in securing an efficient and continuous drainage; (3) in checking that tendency to the formation of exuberant granulation tissue which I believe is largely fostered by the injudicious use of watery solutions; and (4) in affording physiological rest to the inflamed organ, a most important factor in my opinion and one too often neglected in such cases.

Where bone lesions are present or where involvement of the mastoid area is probable surgical measures appear to me not only justifiable but also necessary. I am willing to admit with Mr. White that "much of the doubt which still remains as to the value of irrigation is due to the fact that it seldom gets a *fair trial*," but at the same time consider that the more effectually we shut off where possible the risks of secondary infection from outside sources, the more effectively do we treat the simple suppurations occurring in the cavity of the middle ear.

I am, Sirs, yours faithfully,

Manchester, Jan. 23rd, 1899. W. MILLIGAN.

BORIC ACID POISONING.

To the Editors of THE LANCET.

SIRS,—In an interesting article published in THE LANCET of Jan. 7th Dr. R. B. Wild has called the attention of the profession to the probably frequent annoyances and the more rare, but still possible, dangers produced by the absorption of boric acid into the system. That boric acid is capable of producing skin eruptions when taken by the mouth in medicinal doses for a varying period is quite certain. During the last year I have seen two well-marked cases. In the first case an old man with stricture took half a drachm of boric acid per day for nine days. On the tenth day he began with an irritable papulo-erythematous rash on the face, trunk, arms, and legs. This continued to get worse in spite of treatment and a week or two later I was asked to see him. I suspected the boric acid and suggested it should be omitted. This was done and the rash rapidly disappeared. On resuming the drug the rash and irritation reappeared in two days. The drug was then finally omitted and the rash quickly faded. The urine contained boric acid for some days after the drug was left off. There was no albuminuria. In the second case a middle aged man suffering from enlarged prostate was treated with 15 gr of boric acid per day, the bladder also being washed out daily with boric lotion. After about fourteen days a papular rash appeared on the arms, legs, and trunk, it was very irritable. I ordered the drug to be left off and the rash quickly improved. On resuming it again the rash reappeared, to once more fade on leaving it off. There was no albuminuria. In another case an eruption was produced by biborate of soda. A young girl suffering from epilepsy was shown to me by my colleague, Dr. Duncan Burgess, with an extensive mixed eruption produced by biborate of soda which she had been taking for three or four months. In this case the hairy scalp showed a seborrhœic scaling with loss of hair and the lower part of the trunk and buttocks were covered with an extensive erythematous, papular, and in part vesicular eruption.

In none of these cases were there any other toxic symptoms, but the eruptions in themselves are sufficiently annoying as they will not respond to any local applications and a proper diagnosis is of great importance. As regards the frequency of eruptions produced by boric acid used as a food preservative I cannot speak from personal experience, but it is certainly possible and I quite agree with Dr. Wild that when a case of extensive anomalous eczema appears without any previous hint of a tendency to such affection and persists in spite of treatment it is well to bear in mind the possibility of a boric acid rash and to examine the urine for the drug. The test is so very easily performed and so delicate that any boric acid present will be immediately detected. If after that boric acid is found it remains only to ascertain how it has been taken in. Such eruptions, however, are not usually of a very serious nature, nor are toxic symptoms as a rule present, and provided the medical attendant is aware of the possibility of the cause the condition is quickly relieved. What I should like to draw attention to in connexion with Dr. Wild's excellent article is that the boric acid ointment and fomentations, although as a rule harmless and valuable, may become sources of boric acid poisoning and at times of serious toxic symptoms. My attention was first called to this subject by being asked to see a boy suffering from an intense "scarlatina-like" rash which had come on five days after a burn of the arm and neck. The burn was not very extensive or severe and the boy was doing very well until this rash appeared. He steadily got worse, the rash became more intense, and symptoms of toxic poisoning set in, ending in coma and death. The case is alluded to by Dr. Wild and was published in THE LANCET of April 11th, 1896. Since that time I have been especially interested in this subject and as a result of several observations I have come to the following conclusions:—1. That boric acid used as a dressing for wounds, either in the form of unguentum boracis or fomentations, is absorbed and may be quickly found in the urine. 2. That where there is an extensive surface, as in burns, it frequently produces a patchy erythematous eruption with or without rise of temperature and with slight toxic symptoms 3. That these quickly disappear when the boric acid is left off. 4 That they may also disappear even if the dressing is continued, toleration of the drug occurring in some cases. 5. That if a sufficiently large amount be absorbed relatively to the individual resistance power very grave symptoms or even death may occur.

When it is remembered that the unguentum boracis contains 10 per cent. and the lotio boracis 5 per cent. of the drug and that it is no uncommon thing for an ounce or more of the ointment to be spread on lint, applied to the absorptive surface, and frequently renewed, it will be seen that a very considerable dose may be absorbed in a very short time. Almost all the serious cases of poisoning from boric acid recorded up to now have been where it has been locally applied to an absorptive surface, and I think we may fairly conclude that whilst taken by the stomach it may produce unpleasant skin eruptions of various kinds, it is when applied in large quantities to an absorptive surface that it is most likely to produce dangerous toxic symptoms which may prove the more dangerous because of the lowered condition of the patient and the increased assiduity in the application of the dressings whereby fresh fuel is added to the fire. As regards the character of the eruption which is present in these cases of extensive poisoning I can only say that it is usually erythematous in small rounded patches or running together into considerable areas and it tends to be marked where there is any pressure, but it is very variable and, in fact, is merely, in my opinion, an "erythematous response" which might equally well be called forth by other toxic substances, whether in the form of drug or other toxin.

I am afraid it is too much to ask you to insert any further account of my cases in a letter of this kind, which to be of any service would be of considerable length. Therefore thanking you in anticipation,

I remain, Sirs, yours faithfully,

Sheffield, Jan. 10th, 1899. ARTHUR HALL.

THE MALARIAL PARASITE IN RHODESIA.

To the Editors of THE LANCET.

SIRS,—Mr. Dunley-Owen[1] has published two papers embodying some observations on the malaria parasite as found in Rhodesia. His results are most remarkable and in many points quite at variance with those obtained by the recognised authorities on the subject. As his remarks have hitherto been allowed to go unchallenged we think that it might be well to draw attention to these discrepancies, in the hope that statements so subversive of what is generally believed may be either withdrawn as mistakes or substantiated by full, adequate, and detailed evidence.

In the first place, it is to be noted that he admits that his previous knowledge of the subject was gleaned from "Fagge's Medicine." He appears to be unaware of the writings of Laveran, Marchiafava, Celli, Bignami, Mannaberg, Osler, or Thayer and Hewitson; nor is he aware that malaria is endemic in Italy and has been largely if not chiefly studied there, for he says, "In Europe, for instance, it (i.e., malaria) is scarcely ever met with, and probably only in those who have previously been in the tropics." In the second place, he never mentions how his specimens were prepared, whether they were examined stained or fresh, nor what precaution he took to avoid errors of observation—points of considerable importance when dealing with so-called crescents and pigmented bodies in the soil. Thirdly, he appears to argue that all diseases due to hæmatozoa are the same and for purposes of observation are interchangeable, for he speaks of the malarial bacillus as present in man suffering from malaria and in horses suffering from "horse sickness." It is well known that there is a number of hæmatozoa, the most familiar being halteridium and proteosoma in birds and pyrosoma in cattle, giving rise to diseases in animals quite distinct from malaria in man. As hitherto all attempts to communicate malaria to such of the lower animals as rats, rabbits, &c., have failed, we are loth to accept the transmission of human malaria to rats through the "blind fly."

Again, he states in his second paper that he was mistaken in the bacilli, and that he finds that they were really crescents. Reading his observations in the light of this admission we think that it will be agreed that he is certainly the first observer who has been fortunate enough to see the crescents multiply in the blood; and we think *he alone has observed* the red discs burst and give rise to crowds of crescents. Next, the sporules of which he has seen so many we would *suggest* were blood-platelets; this mistake appears to be very commonly made by those who have not had much experience in blood examination. We are not aware that any other observers have described "blackened corpuscles" in the blood of malaria patients, and it is generally admitted that the leucocytes are normal in number or decreased, and not increased as Mr. Dunley-Owen states.

Lastly, it is difficult to reconcile these two contradictory statements—viz.: (1) "I have made cultivations of the malarial bacillus obtained at this time of the day (i.e. between one hour before and one hour after sunrise) from the grass and the soil but only to the height of four feet from the ground"; and (2) "This led me to inquire what there was in the herbage or the soil which could produce 'horse sickness' and I made microscopical examinations of dew, grass, and soil, but without any discovery." On the whole we feel inclined to agree with Dr. Manson (in spite of the protestations of Mr. Dunley-Owen) that "hitherto all attempts to cultivate the parasite...... have failed."

We are, Sirs, yours faithfully,
ROBERT HOWARD.
WALTER C. C. PAKES.
Guy's Hospital, Jan. 17th, 1899.

REGINA v. REICHARDT.

To the Editors of THE LANCET.

SIRS,—The case of Regina *v.* Reichardt being now closed may I write to second the appeal made in your columns on August 6th, 1898, by Dr. Savage for funds to meet the very heavy expenses which have been incurred by Dr. Reichardt in his defence? I need hardly say that the case is one of the greatest importance both to the medical profession and the public at large. The Commissioners in Lunacy sought to convict Dr. Reichardt of the misdemeanour of taking a lunatic into his house without certificates, notwithstanding their knowledge of the fact that Mr. E. C. Kingsford, Dr. Savage, and I, each of us, had separately expressed the opinion that the patient was not one that ought to be certified. The action of the Commissioners is therefore virtually an attempt to compel medical men to treat all cases of unsoundness of mind by Act of Parliament by placing them under certificates. If the prosecution had been successful in this and in a prior case no one would have been any longer able to take any case of temporary unsoundness of mind into his house except as a certified lunatic. A more cruel, radically unsound, and preposterous doctrine it is impossible to conceive. *With the temporarily* deranged recovered of their madness and prosecuting their medical advisers because of their certification on the one hand, and with the Commissioners prosecuting us on the other hand because of the absence of certificates, God help the unsound of mind who will yet be needing treatment.

Fortunately for those who become temporarily deranged and for those who take them into their houses to treat them—for most of these cases cannot well be treated at home—both Mr. C. D. Sherrard's and Dr. Reichardt's prosecution have proved unsuccessful. But the defendant is saddled with heavy expenses amounting to £700 because he did his duty and the best for the patient. I venture to hope that the medical profession will see that in defending himself he was defending the right of everyone of us to do the best that can be done for every individual patient according to his needs, even though Acts of Parliament when administered according to their letter rather than by their intention may seem to indicate otherwise.

I am, Sirs, yours faithfully,
Jan. 24th, 1899. JAMES F. GOODHART.

THE METROPOLITAN WATER-SUPPLY.

To the Editors of THE LANCET.

SIRS,—In reply to the question raised in your article on this subject in your impression of the 21st inst. I have to *say* that by the *unqualified* term "efficient filtration" I *mean the filtration contemplated by the Act of Parliament* passed in 1852—viz., freedom from opalescence or particles in suspension visible to the naked eye in ordinary light. This is very different from efficient *bacterial* filtration, by which I mean that the water does not contain more than 100 microbes, or their *spores*, per cubic centimetre capable of development on a gelatine-peptone plate. This is a kind of filtration not recognised by Parliament, and the subject is not yet quite ripe for legislation.

I am, Sirs, yours faithfully,
The Yews, Reigate, Jan. 25th, 1899. E. FRANKLAND.

SUSTAINING FARE FOR THE CREWS OF LIFEBOATS.

To the Editors of THE LANCET.

SIRS,—When I became intimately associated with the direction and management of our magnificent lifeboat service I was surprised to find *that no* provision existed for the sustenance of the crews when on cold prolonged *service at sea. I accordingly designed a waterproof tin to* fit the jacket pocket and had it filled with the best chocolate. It was my original intention only to have *them supplied to our local crew*, but really I think every man should have the opportunity to get one who goes to sea in the various lifeboats. Messrs. Cadbury replied to *my queries by most generously* offering to provide tins similar to my design and filled with chocolate to every lifeboat man in the United Kingdom. I accordingly wrote to the secretary of the Royal National Lifeboat Institution, Mr. Dibdin, who warmly acknowledged my scheme and the great offer of Messrs. Cadbury and the matter is before the committee. But the acceptance of it is quite another matter. I believe if you realise *the necessity* of the matter you will help to push it on. Perhaps also you might call for opinions as to the best sort of "emergency ration" for such cold and trying work. *The stuff need not* be used if the service be a short one and so may lie in store.

I am, Sirs, yours faithfully,
C. L. FRASER, F.R.C.S. Edin., &c.
Berwick-on-Tweed, Jan. 23rd, 1899.

"A CASE OF CHRONIC ONE-SIDED PULMONARY ATELECTASIS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 14th an account is given
of a case of chronic one-*sided pulmonary* atelectasis, such
condition being a rare one. A similar case in which the
necropsy revealed the condition was under the care of Dr.
Curnow in King's College Hospital last September or October.
The patient was a middle-aged man who was admitted
suffering from pneumonia and having been a heavy drinker
died from exhaustion. On admission it was found that the
impulse of the heart was situated in the left mid-*axillary* line,
whilst the normal area of cardiac dulness was resonant *on*

percussion. There was apparently nothing to account for this condition. The necropsy revealed the fact that the left lung was simply a small mass in a semi-atelectatic condition, whilst the right lung (upper lobe) had expanded in a compensatory manner and filled the greater part of the left chest, thus obliterating the normal area of cardiac dulness. There was no external deformity of the chest. The organs were shown by Dr. Norman Dalton at a meeting of the Pathological Society of London and a discussion followed as to whether *the condition was congenital or acquired. Dr. Curnow* considered that the left lung had been pathologically destroyed early in life, probably during fœtal life.

I am, Sirs, yours faithfully,
THOS H. GARDNER,
Resident Medical Officer, The Royal Hospital for Diseases of the Chest, City-road, E C.
Jan. 19th, 1899

ANÆSTHETISTS' FEES UNDER THE POOR-LAW.

To the Editors of THE LANCET.

SIRS,—Will you kindly reply in your next issue whether the Local Government Board have ever issued an order sanctioning a fee for the administration of chloroform in operations done in the workhouse or district to medical officers under contract? I have some recollection of having seen some such announcement.

I am, Sirs, yours faithfully,
Jan 22nd, 1899. M D.

⁂ The Local Government Board have issued no order on the subject of fees for the administration of chloroform in operations performed in the workhouse or the parish, but it is not the practice of the Board to raise any objection to the payment of a reasonable fee for assistance "at an operation" (which is the official term for the administration of an anæsthetic), rendered by an outside practitioner to the medical officer of a district or workhouse in the performance of operations of difficulty or danger. It is their rule, however, to call for a short report upon the case from the medical officer before sanctioning the fee. This procedure is of fairly frequent occurrence in large parishes and institutions, and no difficulty is ever raised. Indeed, the Board would probably hold the medical officer responsible, and blameworthy if anything went wrong, if he were to attempt to perform an operation of any importance without adequate assistance of this kind. In institutions where there is an assistant medical officer he is supposed to render such aid, but even in these circumstances, where the operation is one of much difficulty and an assistant is required in addition to the chloroformist, a fee has been sanctioned. The sum approved varies from 1 to 3 guineas, according to the magnitude and duration of the operation.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Progress of the Plague —The Plague Commission

THE progress of the plague in India during the past week was on the whole satisfactory. The new cases reported for the Bombay Presidency are only 2636, as against 3196 the week previously. The deaths have been 2106 against 2576 In Bombay city, however, the returns are unfavourable There was a considerable rise both in the reported plague attacks and mortality. The disease seems to be increasing in virulency, for with 151 cases reported there were 146 deaths, while the previous week recorded 147 cases and 113 deaths. The total mortality was 894, against 742 in the previous week, a rise of 152. The quinquennial weekly average is about 500 The rise in the Dharwar and Bijapur districts was more than counterbalanced by a fall elsewhere.

In the Madras Presidency the situation remained unchanged, but a great improvement took place both in the military and civil stations of Bangalore There was a fall in the number of deaths in the Mysore territory from 416 to 241. The position in the Wardha district central provinces has also improved. On the other hand, plague seems increasing slightly in Broach and in the villages surrounding Poona. No fresh cases have occurred at Rahon in the Punjab, but heavy rain has caused great discomfort to the unfortunate people who have been turned out of their houses, and the huts in the plague camp have been swamped. The greater part of the town has been evacuated, and the remaining inhabitants will soon be cleared out. Karachi records one case and two deaths, *Poona three cases and two deaths.*

The Plague Commission has been sitting in Calcutta, as I said in my last letter. Dr. Justice referred to the 3 cases of plague occurring among the peons of the High Court, in which he attributed the infection to dead rats, many being seen in the neighbourhood, as there was no connexion between the peons and other infected persons. Dr. Bose (native practitioner) thought that the plague was brought from Bombay, but there was no specific instance of men coming from Bombay with plague; it was simply suspicion. A heavy mortality amongst rats was noticed in March, and April and the plague first appeared in Calcutta in April. He thought bubonic cases were infectious. The mortality returns were not satisfactory and plague deaths were registered under other names. Friends registered deaths and there was no system of death certificates. Dr. Hossack thought that there was a factor in the environment of Calcutta inimical to the spread of plague in epidemic form, but what it was he did not know. He said the bustis of Calcutta were in a very insanitary condition. The disinfecting measures adopted were greatly insufficient. He said that the native doctors with Indian degrees rendered no assistance, but resisted the efforts of the officials and helped to conceal cases. Mr. J. N. Banerjee had seen cases of fever with glandular enlargement, but the symptoms were little like the cases of plague which he had attended. There was great difficulty in getting information of cases.

On Jan 3rd Surgeon General Harvey, Director-General of the Indian Medical Department, was examined. So far as he could see the case for inoculation seemed absolutely clear. Though not absolutely preventative it was so to a very considerable degree. Experiments of which he had knowledge were such as to exclude the possibility of error. He did not think people would consent to be inoculated on a large scale before an outbreak. They could not rely entirely on inoculation for coping with an outbreak. It was very valuable but could never be any but an auxiliary to sanitary measures. *Looking at the importance of sanitation he thought it would* be a good thing if they had in India a sufficient number of health officers with good qualifications whose time was actually given entirely *to sanitary work. He* had already recommended this and he expressed the hope that the time would come when every district had its sanitary medical officer. The chief obstacle was the expense involved. Calculation would show that if India spent on sanitation as much as England was supposed to do we should have to spend in proportion to the population £53,000,000 sterling, whereas the actual revenue was only £36,000,000.

On Jan 4th the Plague Commission continued its sittings. Mr. Ferris had no doubt of the existence of plague in the city. Dr Wallace had seen cases diagnosed as plague by others. He disagreed with the diagnoses. He was of opinion that the cases recorded as plague were those of malarial fever of a malignant type.

Mr. Greesbach, Director of the Geological Survey, pointed out that the largest number of plague cases had occurred on the soil covering the Deccan trap and crystalline rocks and only a very small number on the great alluvial belt stretching from the Indian Ocean to the Bay of Bengal. The former formation roughly coincided with the distribution of laterite deposits. On the trap and crystalline rocks 150,929 deaths had been recorded, while on the Indus-Ganges alluvium only 12,936 deaths had occurred, or only 7 88 per cent. His explanation of this apparently striking fact was that the exodus of scared population spread themselves fan-like over the Deccan trap from Bombay.

On the conclusion of their work in Calcutta the Plague Commission will proceed to Agra. They will then go on to Lahore and are timed to arrive in Karachi by Jan. 23rd. Afterwards they will proceed to Cutch Maudvie, Ahmedabad, Baroda, Broach, Surat, and Damaun, reaching Bombay on Feb. 12th, where they will take evidence again until Feb. 20th. The Commission will subsequently go to Poona, Satara, Belgaum, Sholapur, and Ahmednugar. They will embark for F

Mr Jamset

Imperial University in Bombay with the special design to promote higher education in science and scientific and mechanical technology.

Jan. 7th.

PROGRESS IN SANITATION AT DUBLIN.

(FROM OUR SPECIAL COMMISSIONER.)

DUBLIN has not borne a good repute when judged from the sanitary point of view. Old buildings, overcrowded and dirty, bad drainage, and a foul river, have all told their tale in high death-rates and frequent outbreaks of epidemic disease. But it is satisfactory to note that there are signs of improvement. Thus in the five years 1876–1880 the average death-rate of Dublin was 29·5. During the following five years, ending 1885, the average fell to 27·4, and from 1891 to 1895 there was a further decrease to 26·1. In 1897 there was an epidemic of measles and the zymotic death-rate then amounted to 4·5, though the zymotic death-rate, which during the ten years ending 1885 amounted to an annual average of 4·1, had in the following ten years fallen to an annual average of 2·62. The statistics therefore are distinctly favourable in so far as they show an improvement but the death-rate is still high. The fact is that some progress has been accomplished but a great deal still remains to be done. Thus, since the year 1879 the Public Health Department has been engaged in substituting water-closets for the old privies or cesspits. It was no easy matter to effect such a change; nevertheless it may be said that now very few cesspits remain. On the other hand, the closets are often in a foul condition and it is very difficult to induce the lower-class inhabitants to keep them clean. To meet this obstacle the Public Health Act provides that when two or more houses have a closet in common the inhabitants may be collectively prosecuted for not keeping it in proper order. Unfortunately this does not apply to single houses inhabited by two or more families. It is well known that closets used by several families are rarely clean and certainly each tenement should have its own closet. This principle has been practically applied at the Corporation Artisans' Dwellings, Bow-lane, where tenements, though they consist of but one room and are let at only 2*s.* per week, have each their own scullery and closet.

The introduction of water-closets has not, however, failed in Dublin as elsewhere to bring with it a whole list of grievances and necessitates therefore very constant and careful supervision. The borough sanitary engineer, Mr. John G. O'Sullivan, reports that a house-to-house inspection made in a great number of streets rendered it necessary to serve notices to remedy the drainage and sanitary arrangements in the majority of the houses. Though the drains were of more recent date, still the levels were often incorrect and the pipes were not jointed. Frequently there was no interception between the house drain and the street sewer, and where this existed the ventilation consisted of only a two-inch lead pipe taken from the bend connecting the house closet with the soil-pipe. These latter pipes were very generally made of light metal and were not jointed. Other soil-pipes were ventilated in rain-water pipes which abutted close on a bedroom window. The faucets of the light metal pipes were too small to allow their being jointed with lead. Putty was therefore employed. So long as damp weather prevails the smoke test can be successfully applied, but after a dry summer the putty hardens and breaks away and then leakage becomes manifest. Many householders have been thus condemned though their drains were successfully tested a few months previously. Altogether in the course of a year action had to be taken in more than 3000 cases of defective drainage. Great pressure has also been brought to bear so as to ensure the insertion of interceptors between the house drains and the sewers. This is necessary not only so as to protect the houses from sewer air, but also to prevent the soil-pipes being used as rubbish shoots. This used to be a very general practice, and an extra flush or a bucketful of water would carry the rubbish into the sewer. When, however, there is an interceptor a stoppage soon occurs and then it is discovered that the soil-pipe has been used for the disposal of cinders and other household refuse. The result is that, though the number of closets draining into the sewers is increasing yearly, the sewers are cleaner and more free from heavy deposits than formerly. This is due to the more general use of interceptors, and their introduction has reduced the cost formerly incurred in cleansing the sewers.

The necessity of abolishing cesspits which so generally contaminate the subsoil and of rendering all drain-pipes absolutely watertight has been set forth in a striking manner by Sir Charles A. Cameron, superintendent medical officer of health of Dublin. He has caused special inquiries to be made concerning 4000 cases of typhoid fever in relation to the subsoil. It was then ascertained that the proportion of cases of typhoid fever was 50 per cent. more frequent in houses built on gravel than in houses built on the boulder clay. The fact is that the bacillus typhosus is aerobic and obtains oxygen far more freely in loose gravel than in stiff clay. In the gravel soil the germs can travel a long distance and freely multiply. Dublin has an excellent water-supply, the plumbing work is equal to that of other towns, and yet typhoid fever continues to prevail. It is therefore most urgent to prevent the contamination of the subsoil, especially if it is of sand or gravel, and in this respect Sir Charles Cameron informed me that within the last few years no less than 10,000 water-closets had been built. Nor are any clay or putty joints now allowed. These are preferred by the builders because, when necessary, the pipes can be disjointed and removed without breaking. In Dublin, as in many other large towns, the drainage of the poorer-class houses is often in better condition than that of the houses inhabited by wealthier people. This is due to the fact that the former are more frequently inspected. It is not so easy to find a pretext to test the drains of a high-class residence.

While the house drains have been frequently inspected and improved the main sewers have not been neglected. Some twelve miles of main sewers were recently surveyed, levelled, their condition examined, and more than 800 connexions with house drains inspected. That, however, these sewers are not self-cleansing is proved by the fact of the difficulty which arises with regard to their ventilation. The ventilators which terminate on the surface of the roadway have in a large number of cases, the engineer reports, been the cause of much complaint, more especially in narrow streets and avenues. If the sewer was clean—that is, if it did not contain any deposits—it would not occasion a perceptible odour. It is when the receding water leaves these deposits bare that the greatest nuisance arises. But the fact is that formerly sewers were not built on self-cleansing principles; and even to-day these exist only in exceptional instances. To prevent sewer air reaching the street in such a condition as to create a nuisance Sir Charles Cameron has invented a dome-shaped hood made of porcelain clay and plaster-of-Paris. This is placed over the ventilator outlet and absolutely prevents any sudden gust coming up. The air can only filter through slowly and it seems to lose its objectionable odour in the process. This certainly does away with the apparent nuisance, but this is not a sufficient reason to recommend the invention. No good purpose is served in merely masking a bad odour. The real object of perfect sanitation is to remove the cause that gives rise to the odour, and till this can be done such foul emanations as do exist had better escape into the street. The question arises whether this sewer-air filter really deodorises the air or only lets it through so slowly and in such small quantities that the odour becomes imperceptible. Whatever may be the answer to this question the next point is, What happens to the pathogenic germs, if any? Are they retained inside the filter? and if so should they be thus retained and imprisoned? Is that the true method of getting rid of them? But supposing that the filter is satisfactory from the bacteriological point of view, does it not impede the ventilation of the sewers? It is necessary to bear in mind that the prevention of a bad odour is but the secondary object; the first and most essential necessity is thoroughly to ventilate the sewer. The atmosphere of the sewer does not, however, obligingly force its way through apparatus placed on purpose to receive it. Sewer air invariably makes for the line of least resistance. This is why the charcoal or coke-trays have fallen into disuse. Doubtless they would have answered their purpose very well but for the fact that the sewer air instead of coming through them often found an easier exit by some leakage or an untrapped or insufficiently trapped soil pipe. Considering that the construction of the main sewers, of the branch drains, the joints of the pipes, &c., is not yet perfect, such an obstacle as a porcelain air-filter placed over the sewer ventilator may, while preventing perceptible odours in the street, increase the amount of sewer air which enters the houses. Such a contrivance may render good service, but only on condition that the sewer and its ramifications are absolutely air-tight in all other directions.

One very great improvement will be realised in the course of about two years. The numerous sewer outfalls into the Liffey will all be abolished. A loan of £350,000 was sanctioned for the extension and amelioration of the main drainage of the city. A main collector is in course of construction to carry all the sewage to Pigeon House Fort where it will be received in large tanks and treated chemically. The heavy sludge will be taken out to sea in tank boats, and the effluent discharged into the bay when the tide is running out. The addition of two powerful pumps will insure the continued flow of the sewage in all conditions of the tide. Thus in any case the Liffey will no longer be contaminated by the raw sewage of the town.

By far the most difficult problem in Dublin is that of the housing of the poor. There are some 32,000 families living in 48,000 tenement rooms. There is very little work for these people to do, for there are comparatively few industries in Dublin Model artisans' dwellings have been constructed, many philanthropic efforts have been made—notably by the late Mr. Peabody and by Lord Iveagh—but the people who most need to live in better houses are unable to pay the rents charged in these model dwellings. What is really wanted is better employment for some 20,000 people. How can families who often do not earn 10*s.* a week pay 4*s.* 6*d.* for rent? The result is that the model dwellings are inhabited by the better class of artisans and the slums remain in the same deplorable condition. The matter, however, has not been left solely to the 5 per cent. philanthropists. The corporation has itself built some model dwellings and here tenements are to be had at 2*s.*, 1*s.* 9*d.*, and even as low as 1*s.* 6*d.* a week. Unfortunately there are so few of such tenements at present that they have not materially affected the situation. The private landlords who let rooms to the poor are for the most part only leaseholders or yearly tenants They cannot under these conditions spend much on improvements. It would not pay them to provide proper accommodation for 1*s.* or 2*s.* a week. But this is possible for a municipality which can borrow money at a very low rate of interest and is not hungering after large profits. The borrowing powers of municipal authorities, as Sir Charles Cameron points out, are, however, limited to two years' valuation of the town for rateable purposes. This was a very wise provision when the money borrowed was only spent for unproductive purposes; such as, for instance, parks, sewers, &c. But slaughter-houses, markets, artisans' dwellings, &c., bring in good and reliable revenues, and it is claimed that for such purpose the powers of borrowing should be extended. In any case, the position stands thus: either the powers of the municipality must be extended so that it may be able to supply a very large number of tenements at from 1*s* to 2*s.* per week rental, or else new industries must be started providing more work and better pay for many thousands of people. Short of this it is difficult to see how overcrowding and insanitary conditions can be prevented.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Hulme Sewer Fatality.

THE fourth sitting of the Manchester City Coroner's Court brought to a conclusion the inquiry into the cause of death of two men, John McGregor and W. C. Hodgson, who were suffocated in a sewer in December last. The occurrence was mentioned in an annotation in THE LANCET of Dec. 24th. The result is not altogether satisfactory. The evidence showed that in one case a connexion had been made between a drain from certain works and the main sewer which had never been notified to the corporation Dr. Bailey, assistant lecturer on chemistry at Owens College, said that "in his opinion the gas" (presumably sulphuretted hydrogen) "must have been discharged into the sewer in a perfectly pure state and must have travelled two miles before it got to Walcombe-street and that the men were killed by a sudden rush of gas." Mr Thomson, the chemist, said there was a considerable quantity of acid in the sewer and that where they found sulphuric acid there was a strong smell of naphtha and benzoline. He had taken samples at different times "and found that on the morning of the 22nd December in one outburst 232½ lb. of acid came down." Other evidence was given showing that in some way or other a larger quantity of deleterious matter got into or was turned into the sewers but from which of various works it came was apparently not capable of proof. The coroner said that it was an offence to put into sewers gas or chemicals which might be injurious to health. The police confessed that they had failed to get definite evidence as to the source of this poisonous gas. The verdict was that the deaths had been caused by poisonous gas, but there was not evidence enough to fix the responsibility on any particular person or firm and they trusted that the Corporation officials would "examine with increased vigilance the effluent from works known to be producing dangerous substances." There are too many of these sewer accidents, as they are called; many occur which are not quite fatal and are not heard of. They are not accidents but are the natural result of a disregard for consequences and, we must suppose too, of the low estimate put on the lives of the men who work in the sewers by the proprietors or the managers of such works.

Ladies' Health Society.

The annual meeting of this most useful society was held in the Manchester Town Hall on Jan. 17th under the presidency of the Lord Mayor. Though its work may be thought slow and tedious and though "the teaching little by little and with oft-repeated iteration the elementary laws of domestic sanitation" may be long in leavening the dense mass of apathy and ignorance as to matters affecting health which prevail among the many thousands of the working population of Manchester and Salford, it is yet one of the best possible agencies for bringing about a gradual improvement in their knowledge of the art of living. The women of the working population have practically all domestic sanitation in their hands so that the best way of ensuring cleanliness of house, clothing, and person with efficient ventilation is to secure their interest and intelligent help. It is a work of house-to-house detail and must, to be of much use, be so carried out as not to wound the sensitive pride of the poorer classes, and on the whole this is fairly well achieved. "The health visitors, being superior women belonging to the class among whom they work, have a fellow feeling and a more thorough understanding of the difficulties, the needs, the failings, and the sorrows of the poorer classes than women brought up in greater refinement and luxury would have. The lady superintendents strengthen and supplement this by an element of outside freshness, by wider views, help of various kinds, support and cheer for the health visitors, and sympathy for all." The society is in the unwonted position for a charity of having a moderate balance in hand, but lady voluntary helpers are wanted. "There were districts in Salford ready to be taken up; the funds were provided and for these they wanted lady superintendents." The Lord Mayor testified to the good work of the society among "the poorest of the city" and to its working in harmony with the corporation, by whom 9 of the 16 visitors in Manchester are provided. Dr. Leech, Dr. Niven, and others spoke. The Rev. J. E. Mercer mentioned the work in Angel Meadow which, in contrast to its name, is one of the worst places in the city and said "the society was on the right track of slow and steady leverage at a huge mass which had to be lifted and could only be lifted by methods such as those used by the Ladies' Health Society." Manchester is no doubt typical of many other towns and it would be well if similar societies were at work through the country.

Jan. 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Urban Mortality in Scotland in 1898.

A SUMMARY of the particulars in the Registrar-General's monthly returns as to the eight principal towns of Scotland (the issue of which series for last year has just been completed) shows that in 1898 there occurred in these towns collectively 32,153 deaths, which for an estimated population of 1,568,536 gives a death-rate for the year of 2·05 per cent. This is a decrease upon the general rate for the previous year which amounted to only 2·12 per cent. of the inhabitants, being an exceptionally low figure. Of the 32,153 deaths 15,333 occurred in Glasgow, 5796 in Edinburgh, 3460 in Dundee, 2682 in Aberdeen, 1362 in Leith 1584 in Paisley, 1308 in Greenock, and 628 in Perth; and the individual death-rates in these respective towns were as follows, beginning with the lowest:—Leith, 17·85 per 1000 of the population; Aberdeen, 19·10; Edinburgh, 19·60; Perth, 20·50; Paisley, 20·97; Dundee, 21·02; Glasgow, 21·17; and Greenock, 21·38. The deaths of children under five years of age numbered 12,753, the aggregate infantile mortality being thus 39·6 per cent. of the total deaths. In every 100 deaths in Perth 26·2 were of children under five years of age, in Edinburgh the percentage was 32·3, in Greenock it was 37·8, in Paisley it was 38·5, in Leith it was 40·2, in Abereeen it was 40·3, in Dundee it was 42·0, and in Glasgow it was 42·6. Of the 12,753 deaths of children under the age of five years, 7756 were those of children under one year of age. Of the aggregate of 32,153 deaths, 5004 were due to specific febrile or zymotic diseases, 10 to parasitic diseases, 145 to dietetic diseases, 6057 to constitutional diseases, 2276 to developmental diseases, 16,140 to local diseases, 1235 to violence, and 1286 to ill-defined and not specified causes. To speak more particularly as to the causes of death, 3497 deaths were due to miasmatic diseases, 3601 to diseases of the nervous system, 2775 to diseases of the circulatory system, and 6004 to diseases of the respiratory system. With regard to the zymotic diseases, there were 2 deaths from chickenpox and 1 from small-pox, 914 from measles, 389 from scarlet fever, 28 from typhus fever, 336 from influenza, 1198 from whooping-cough, 252 from diphtheria, and 350 from enteric fever. There were also 1074 deaths from diarrhœa. The deaths from measles were most marked in Glasgow from January to May inclusive, in Dundee in June and July, in Paisley in May and July, and in Aberdeen in December. Fatal cases of whooping-cough were most marked in Glasgow from January to May inclusive and also in August and October, in Paisley from January to July inclusive, in Aberdeen in April, August, September, and October; in Greenock in January, February, and October; in Perth in August, in Leith in December, and in Edinburgh and Dundee in April. Enteric fever was marked in Paisley in September and November, and scarlet fever in Greenock in January and December. Influenza prevailed in Edinburgh in March and April, in Paisley in March, and in Dundee and Perth in April. The deaths from zymotic diseases in the eight towns collectively were 10·9 per cent. of the total deaths, as against 15·3 in the preceding year. In the eight towns together there were last year 2735 deaths from pneumonia, 2590 from bronchitis, 2985 from phthisis, and 2123 from endocarditis. The mean temperature of the eight towns in 1898 was 48·9° F., and the mean total rainfall was 35·08 in. Appended to the returns are particulars as to forty-four other towns with a united estimated population of 713,488, the individual populations ranging from 48,320 to 2324 and fourteen of the towns being above 20,000. The aggregate mortality in these forty-four towns last year was 13,111, or 1·84 per cent. of the estimated population, which is less than the rate for the eight principal towns together. Of the deaths there were 4 from chicken-pox, 395 from measles, 169 from scarlet fever, 356 from whooping-cough, 80 from diphtheria, 199 from fevers (typhus and typhoid), 5 from cholera, 671 from diarrhœa and dysentery, 64 from croup and laryngitis, 2255 from bronchitis, pneumonia, and pleurisy, and 1246 from consumption.

Physical Training in Scotland.

A good deal of interest has been aroused in Edinburgh and other places throughout Scotland by the publication of two letters from General Chapman. The first was sent to School Boards and advocated the physical training on the army model of the pupils attending the schools and the establishment of gymnasia. The second has been addressed to the Lord Provost of Edinburgh and advocates the formation of schools-at-arms and of public gymnasia for the physical training of our youths. All schemes which have as their object the physical well-being of the youth of the land commend themselves to the profession, and interest in physical training is not only good in itself but adds an interest to the life of young men which acts as a considerable preventive. The warm advocacy of these schemes by General Chapman will, there is little doubt, bear some fruit.

Edinburgh Dental Hospital School.

The annual meeting of this institution was held on Jan. 23rd under the chairmanship of the Lord Provost. From the report it appears that during the year the number of cases of conservation dealt with was 7234; the extractions numbered 11,600 teeth; the number of persons to whom anæsthetics was administered was 959, of whom 293 were given chloroform, 620 nitrous oxide gas, and 46 nitrous oxide and ether. The number of students on the roll was 55, of whom 23 were in their first year. There was still a debt of £2000 against the institution.

Out-patients at the Edinburgh Royal Infirmary.

It is worthy of note that the serious attention of the managers of the Edinburgh Royal Infirmary has been drawn to the increase in the number of out-patients. The committee of contributors expressed their belief that a considerable number of patients who could well afford to pay for medical advice were taking advantage of that department. This question has hitherto been shunned and it is certainly noteworthy that the complaint comes from the management and not from the honorary staff.

Proposed Additions to Leith Hospital.

The directors of Leith Hospital have now matured plans to meet the views of the committee who have charge of the scheme for commemoration of the Queen's Diamond Jubilee, so that the scheme will probably take practical shape in the course of a few months. The proposed extension will allow of an increase of 27 beds in the King-street Pavilion and the hospital when completed will contain 102 beds and 2 isolation rooms. There will, moreover, be erected in addition a new kitchen, laundry, and nurses' home. The kitchen and laundry will be provided with steam-power. The nurses' home will accommodate nearly 30 nurses. The Diamond Jubilee Fund amounts to only about £5000, whereas the total cost of the new buildings, including machinery and plant, will amount to between £17,000 and £20,000.

St. Andrews University.

The installation of Mr. James Stuart, M.P., as Lord Rector took place on Jan. 23rd. At the same time honorary degrees were conferred on various persons, Sir William Broadbent, as representing medicine, and Mr. Buckle, editor of the *Times*, as representing the press, receiving the degree of LL.D.

Glasgow Microscopical Society.

The society met on Jan. 17th to hear a lecture on "The Development of the Heart" by Mr. J. F. Gemmill, M.A., M.B. Glasg., Lecturer on Embryology in the University. After a preliminary comparison of the circulatory mechanism in the various groups of the vertebrate series Dr. Gemmill described in detail the development of the mammalian heart and its various parts. He remarked upon the anticipatory character of the appearance of some of the parts when the organ was regarded from a physiological point of view, showing how in several respects stages of structure were reached in advance of physiological requirement. The generalisation of Haeckel that every animal in its individual development exhibits an epitome of the stages through which the genus has been evolved was criticised in detail with a somewhat adverse conclusion though its value both in the study of embryology and as an aid to classification was allowed. The President, Dr. James Rankin, proposed a vote of thanks to the lecturer and this was heartily accorded.

Royal Infirmary, Glasgow.

A movement to promote the election of two ladies to the board of management of the Royal Infirmary has now taken definite shape and at the forthcoming annual meeting it is understood that Mrs. J. W. Napier and Mrs. G. R. Mather will both be nominated. At the last annual meeting of the Western Infirmary a similar resolution was submitted and was only withdrawn on an official undertaking to consider the question.

Jan. 25th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Orthopædic Hospital.

THE annual meeting of the governors and subscribers to the Dublin Orthopædic Hospital took place on Jan. 18th, under the presidency of the Right Hon. Lord Justice Walker. The report, which was read, showed that the institution was in a most satisfactory condition and that what it most required was enlargement. A lease of ground adjoining the hospital in Great Brunswick-street was acquired in March last, but it is now likely that the Corporation of Dublin will succeed in a compulsory purchase of this plot as a site for a fire-engine station. In that event some other plan must be adopted for the enlargement of the hospital. A vote of thanks to Lord Justice Walker was proposed by the President of the Royal College of Surgeons in Ireland who is one of the medical staff of the hospital.

Royal University of Ireland.

A meeting of Convocation of the Royal University of Ireland was held in the University buildings on Jan. 19th, the Rev. Dr. Hamilton, President of Queen's College, Belfast, occupying the chair. The following members were unanimously re-elected representatives on the Senate: Sir William Thomson, M.A., M.D. R.U.I.; His Honour James J. Shaw, M.A.; Dr. Thomas Sinclair; Mr. Edward Cuming, M.A.; and the Rev. M. Leitch, M.A.

Action for Libel by a Medical Man.

The medical officer of the Glenties Dispensary, County Donegal, has recently brought an action against some members of the Dispensary Committee and the proprietor of the *Londonderry Sentinel*, jointly and separately, for libel alleged to be contained in a resolution passed by the Dispensary Committee. An application was made in the Queen's Bench Division, Dublin, on Jan. 22nd, before Mr. Justice O'Brien and Mr. Justice Gibson on the part of the defendants to change the venue from Dublin to Donegal, in which county the cause of action arose. There was a very strong muster of eminent members of the Bar, but although Mr. Drummond, Q.C., in opposing the motion stated that the charges made against his client were of a startling character, the application was granted and the case will be tried at Donegal.

Belfast Royal Hospital.

At the annual reunion of the committee of the working men in connexion with the Royal Hospital, it was reported that the amount of subscriptions received during the past year was the largest on record since the formation of the working men's committee—viz., £2534 1*s.* 11*d.*—in addition to £50 received from the employés of the Belfast Street Tramways Company, making the total amount received £2584 1s. 11*d.* The committee, which meets in the Board-room of the hospital once a fortnight, is composed of representatives from the different firms whose workers contribute to the funds of the hospital and are elected from amongst themselves by the subscribers. Each member is appointed in turn to act as orderly whose duty it is to visit the hospital at stated intervals and to report the result of his visits. By this means the committee say that they have succeeded in retaining the confidence of the people whom they represent in the management of the hospital. The committee tender their best thanks to the medical staff for the very efficient services rendered to the patients placed under their care.

Nursing in Workhouses in Ireland.

At a meeting of the Lurgan Board of Guardians held on Jan. 19th a letter was read from the Local Government Board on the subject of hospital nursing, intimating that it was proposed to prescribe that a qualified nurse must have been two years in a recognised clinical hospital and have obtained therefrom a certificate of proficiency in trained nursing. Such certificate would be admissible from a clinical hospital only, unless the nurse had been trained in a non-clinical hospital having at least 150 beds and possessing a resident surgeon and two visiting surgeons and unless the nurse had attended lectures and received a course of instruction in the nursing of contagious diseases. Dr. Darling (surgeon to the Lurgan Union Infirmary) said that he had a note from Mr. Stafford (Medical Commissioner of the Irish Local Government Board) saying that the definition of a trained nurse now laid down would only apply to nurses drawing half salaries from Government, but the qualifications were framed to exclude workhouses as training grounds. The Lurgan probationers would be recognised as charge nurses, but not as nurses entitled to receive the proportion of Government salary. The Local Government Board was establishing two classes of nurses, a superior and an inferior. There were only two workhouses in Ireland (Belfast and Dublin) which would come up to the recognised standard, and he trusted that public opinion would be brought to bear on the matter and that the Local Government Board would change its mind. The guardians agreed to appeal to the other Poor-law boards in Ireland on the subject.

The Conscientious Objector.

The first application made in Belfast for exemption under the new Vaccination Act took place in the Summons Court of that city on Jan. 23rd, when a man applied for an exemption certificate as he had a conscientious objection to have his child vaccinated. The resident magistrate said he had no power to grant a certificate, and the clerk of the court pointed out that the Act did not apply to Ireland or Scotland. In this dilemma the applicant inquired what redress had he, to which the clerk gave the very significant reply: "The only redress you have is to get your child vaccinated." On the suggestion of the resident magistrate the applicant said that he might probably go to England which apparently is the special El Dorado of the conscientious objector.

Medical Men and the New Urban and County Councils.

The Local Government Board have just made an order that no paid officer engaged in the administration of the Poor Relief (Ireland) Acts, 1838 to 1898, shall be eligible to serve as a county councillor under the Local Government (Ireland) Act, 1898. If this applies to county borough councillors, as it appears it does, it is said that it will disqualify two gentlemen who have been elected members of the Belfast Corporation—Alderman Bigger, M.D. R.U.I., who is physician to the Union Fever Hospital, and Dr. Barron, who is dispensary medical officer. The Local Government Board should have made a clear pronouncement on this question before the elections.

The Urban District Councils.

The new urban councils under the recent Local Government (Ireland) Act have just been elected and are settling down to work. In Lisburn Mr. St. George has been elected chairman and in Newry Mr. McCartan, J.P. At Ballymena notice of motion was given that immediate steps be taken to obtain an abundant supply of water to the town, and at Bangor, after a long discussion on the same subject, a committee was appointed to take the matter of the water-supply into consideration and to report from time to time to the board. Mr. Moore, one of the newly-elected councillors, is on this committee.

Election of Medical Officers at Rathdown Union.

The principal business which came before a very large meeting of the Board of the Rathdown Union, which took place on Jan. 11th, Lord Powerscourt being in the chair, was the election of a medical officer to the workhouse. There were no less than eleven candidates for the appointment, to which Mr. Pim was ultimately elected after many ballots.

Jan. 24th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

AT the meeting of the Academy of Medicine held on Jan. 10th Professor Proust, the Inspector General of the Sanitary Department, read a long report on the Geographical Distribution of Plague in Asia and Africa and referred to the dangers which would arise from an extension of the malady to Europe. He reminded his hearers that the Venice Convention of 1897 had drawn up a set of regulations which should have the effect of protecting Europe from the danger of propagation of the Indian plague. Unfortunately, however, some of the measures adopted had not been carried out in their entirety, while others had never been acted upon at all. With regard to the question of the spread of plague by means of laboratories, as had recently happened in Vienna, strict precautions to avoid this happening again had been taken in every country. In France, for example, a commission composed of MM. Roux, Duclos, Brouardel, and others has just proposed to the Government a number of very strict regulations to apply to all laboratories. These regulations provide that no one shall be allowed to remove cultures from the precincts of the laboratory and that even within the laboratory they shall only be handled by trained workers under the personal surveillance of the chief who shall also be responsible for the work. As to international measures the question is far more delicate, and M. Proust lamented that certain nations for fear of putting obstacles in the way of their trade only carried out inspection and disinfection in a very perfunctory fashion. He recalled to mind the possible epidemics which might have broken out in London owing to the arrival in that city of infected persons who had escaped the inspection organised on the Suez Canal. Thanks to the energetic measures taken by the sanitary authorities of London nothing untoward occurred. It was, however, by no means impossible that if more care were not taken at Suez the plague would one day overleap the barriers provided against it and establish itself in Europe. M. Proust cited the case of the *Caledonia* of the Indian Mail Service. After reflecting severely upon the conduct of various sanitary authorities and officials with regard to this vessel M. Proust mentioned the instance of the *Golconda* and the *Mahallah*. M. Proust concluded by earnestly appealing to the sanitary authorities of every country to demand of their respective Governments that no infractions of the rules of the Venice Convention should be allowed merely in the interests of commerce.

The Use of Blue Glass in the Diagnosis of Syphilis.

At the meeting of the Society of Dermatology and Syphilography held on Jan. 12th M. Jullien said that since the year 1895 he had been in the habit of employing blue glasses as an aid to the diagnosis of syphilitic eruptions. He uses a simple binocular fitted with lenses made of cobalt blue glass. Only a moderate amount of light is necessary and the practitioner must remember that all the red and yellow rays are cut off. Owing to this the field is uniformly blue and the matter resolves itself into differences of tint in the depth of the blue colouration. This method is valuable for the diagnosis of eruptions even before they are visible to the naked eye and also for the diagnosis of aborted eruptions. M. Jullien does not affirm that one can absolutely diagnose syphilis in this way by one examination, but he insists on the necessity of many and long-continued observations. Weeks, months, sometimes even years after the disappearance of a syphilitic rash a blush remains visible by means of the blue glass, showing that the skin is still impregnated with germs and pointing to the necessity for continuing treatment. Those spots which might be considered as fresh are really only the outcome of the original eruption. This method is not only useful in the diagnosis of tertiary syphilis and the scars left by it but also in the pathological anatomy of that disease.

Hygiene for Barbers.

At a recent meeting of the Council of Hygiene and Public Health of the Department of the Seine M. Bezancon, head of Division 2 of the Prefecture of Police, read a communication from M. Dupuy, head of the Ministerial Council, dealing with the use of lotions for the hair made upon an ether or light petroleum basis. Professor Bourgoin, in accordance with a regulation put forward by the Council of Hygiene, had laid before the Minister a report dealing with the dangers accruing from the use of these preparations. The Consulting Hygienic Committee of France, to which body the matter was referred, reported in its turn on the dangerous nature of of these lotions and pointed out that they did not possess the properties attributed to them. The Minister therefore decided that the use of these preparations should be checked and that the best way was to make use of the Hairdressers' Association as an intermediary to point out to the trade the dangers of these lotions, dangers which were not accompanied by any compensating advantages. The hairdressers, whose interest it is to give satisfaction to their customers and not to expose them to risks, at once agreed to the demands of the Minister. In thus prohibiting the use of lotions made with light petroleum the Administration has acted as it should do in its capacity of being responsible for the public health, and if accidents should happen in future the Administration will at all events be free from blame.

The New Sanitary Department at Frioul.

The new sanitary station at Frioul, near Marseilles, has just been fitted with as perfect a plant as possible. A wooden landing stage permits all merchandise to be rapidly loaded or landed. The landing stage is divided into two sections, each furnished with an up and down railway for waggons. One-half is for the landing of infected goods and the other for the loading of those which have been disinfected. Bales, cases, and baggage of all kinds are lifted on to the stage by cranes capable of handling a weight of 1200 kilos. They are then carried by the goods waggons to a large disinfecting shed where by means of an ingenious system of tubes they are saturated with disinfectants. Goods suspected of being particularly dangerous go through two stoves at the end of the shed. After these operations the goods are carried down to the wharf used for disinfected goods and are then loaded into the ship which brought them. Identical measures are taken for the disinfection of passengers. The disinfecting cabins are divided into three: in the first the passenger undresses and his clothes are promptly taken to the stoves where they are disinfected; in the second the passenger is douched; and in the third he gets his clothes back and is allowed to dress.

Jan. 24th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Catheterisation of the Ureters.

THE subject of catheterisation of the ureters has recently been discussed by the Berlin Medical Society and has led to a series of very animated debates extending over several meetings. Dr. Casper reported 3 cases where a good result was obtained by this procedure. In the first case the patient was a man in whom total anuria had been caused by incarceration of a calculus in the ureter, but after catheterisation and injection of sterilised oil the calculus was discharged. In the second case the patient was a woman, twenty-eight years of age, suffering from severe pyelitis, from which she recovered after catheterisation and the injection of a 1 in 1000 solution of nitrate of silver. The third patient was a man, thirty-four years of age, having a tumour of the right hypochondriac region which at first was believed to be an echinococcus cyst, but on puncture was found to be the enlarged pelvis of the kidney and by catheterisation of both ureters it was ascertained that the urine from the right kidney was purulent whilst that from the left was normal. Catheterisation and injection of solution of nitrate of silver caused fever, but nevertheless after a series of injections the pyelitis disappeared and the urine became normal. Dr. Casper pointed out that in cases where a free communication existed between a renal abscess and the pelvis of the kidney injections of nitrate of silver may be able to effect a cure. Moreover, extirpation of a kidney ought not to be performed until the soundness of the other kidney had been ascertained by catheterisation. Dr. Casper's views were strongly opposed by Professor Israel who in a very detailed statement warned his hearers against attaching too much importance to this procedure. In 81 operations for pyonephrosis performed by him there were only 3 in which catheterisation of the ureters might possibly have been of any use. His general conclusions were (1) that catheterisation gave little or no information as to the condition of the second kidney when nephrectomy was contemplated, as under certain conditions normal urine may be passed by the catheter although the kidney is seriously affected; (2) that affections of the second kidney were not in every instance contra-indications of nephrectomy; (3) that catheterisation was unable to ascertain the presence or the nature of an obstacle; (4) that the presence of blood in the urine obtained by catheterisation might either be due to hæmorrhage from the kidney or to injuries produced by the catheter; and (5) that the operation is liable to produce infection. In the ensuing discussion Dr. Kutner emphasised the impossibility of obtaining sufficient sterilisation as the optical apparatus was liable to be destroyed by the application of steam. Dr. Landau said that in gynæcological operations, as for instance in extirpation of the uterus for carcinoma, &c., the method was useful as a means of avoiding injury to the ureter. Of the other medical men taking part in the discussion Professor Litten and Dr. Wossidlo opposed the method, whilst Professor Posner, Dr. Mainzer, and Professor Dührssen expressed a more favourable opinion.

The State Examination in Medicine.

An Imperial Commission composed of delegates from the different states of the empire recently met in Berlin to discuss alterations of the State examination. It is by passing this examination, as the readers of THE LANCET will remember, that medical students obtain their qualification to practise in Germany. The principal and most important paragraph of the Commissioners' resolutions is the recommendation that the preliminary examination (*Abiturientenexamen*) passed at a "gymnasium" shall be obligatory on students of medicine. By this attitude the hopes of those who plead the cause of the "realgymnasia" have been disappointed. In the "gymnasia" the study of the Greek and Latin languages is preponderant, whilst in the "realgymnasia" modern languages, physics, &c., are the principal subjects. A classical education will therefore continue to be an essential condition of entering on a medical career. The Commissioners recommend that the medical curriculum should be of at least five years' duration, whereas hitherto four and a half years have been sufficient, and that this time should be spent at universities of the German Empire exclusively; under certain circumstances a portion of the curriculum may be taken in foreign universities. It is proposed that the examination in anatomy and physiology, which according to the present regulations takes place twice—viz., at the first and the second professional examinations, shall henceforth be removed from the State examination and be wholly included in the first professional examination (*tentamen physicum*). It is also recommended that the subjects of examination shall be: general pathology and pathological anatomy, pharmacology, clinical medicine, surgery, gynæcology and obstetrics, diseases of the eyes, diseases of children, mental diseases, and hygiene; foreigners to be subject to the same conditions as Germans. The resolutions of the Commission are of course of a preliminary character only and have to be sanctioned by the Federal Council which is the only authority competent to give a final decision. The German members of the medical faculties of Switzerland have availed themselves of this opportunity to ask the German Government to establish a certain amount of reciprocity in the qualifications of both countries. They especially desire that the testimonials of Swiss and German universities may be of equal value, so that German students may be able to take their curriculum in Switzerland without losing a portion of the assigned time. Swiss medical men would like to hold appointments in German universities not only in laboratories and similar teaching institutions, but also in clinics and university hospitals for which a medical qualification is required. It is not probable that the Government will agree to meet the wishes of the Swiss professors as the number of native candidates for vacant places is great enough to make the coöperation of Swiss medical men unnecessary.

The Medical Courts of Honour.

In the speech from the Throne by which the present session of the Prussian Diet was opened a Bill relative to medical courts of honour was announced. This matter, to which allusion has already been made in the columns of THE LANCET, has been discussed at great length in the medical chambers as well as in the different associations of medical practitioners. The opinion of the profession was divided as to the advisability of this measure, but the Government has resolved to bring the matter to an issue. Owing, however, to the great amount of business claiming the attention of the legislature it is very uncertain whether the Bill will be passed or even discussed before the session is closed.

The late Professor Gurlt.

Professor Gurlt, who died in Berlin on Jan. 8th, is universally regretted by the medical profession and especially by its surgical branch. Although engaged in surgical practice for a very short time he contributed largely to the science and history of surgery. As permanent secretary of the German Surgical Association he had to make the arrangements for the annual meetings of this important society and to publish its proceedings. During the last few years he had the management of the collective investigation on anæsthetics. He was one of the founders and principal members of the German Red Cross Association and long before the foundation of this society called public attention to the necessity of greater care being taken of sick and wounded soldiers in war-time. His name will always be famous as one of the historians of surgery. Scarcely a year before his death he published his great work on the "History of Surgery during the Middle Ages and the Renaissance," the result of more than ten years' study. The deceased was extremely modest and unostentatious and not widely known to the general public, but he enjoyed great popularity in medical circles. Professor Gurlt was the editor of the *Archiv für Klinische Chirurgie* and co-editor of the Virchow-Hirsch *Jahresbeiträge*

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Health of Leo XIII.

GIBBON ironically congratulated himself on the number of clergymen whom he had been the means of promoting by "replies" to his famous thirteenth and fourteenth chapters. In like manner the reigning Pontiff may contemplate with satisfaction the many journalists whom he keeps alive by reporting on his health. This latter is really an "industry," if we may judge from the rapidly recurring paragraphs on "le salut du Pape," or "la salute del Papa," or "die Gesundheit des Papsts," which throng the European press when contemporary affairs are slack or wanting in interest. If the official journal of the Vatican—the *Osservatore Romano*—fails to chronicle the usual audiences or receptions its silence is at once the signal for the familiar paragraph in which the word "deliquio," or "défaillance," or "Ohnmacht" is sure to appear, according to the reporter's nationality. The week has just closed with an unusually pronounced crop of these newspaper exanthemata or (fitter phrase) journalistic "rash." On inquiry the condition of his Holiness is found to resolve itself into a cold in the head, an ailment not unknown even in mid-winter and in a hard-working ecclesiastic verging on ninety years. The facts are these. Dr. Lapponi on the morning of Jan. 18th advised his august patient to keep his bed, as he was certainly suffering from a "raffredore di testa" which, in spite of every precaution, he had contracted in this abnormally inclement season. His Holiness did so and the next morning felt distinctly better. On the 20th he still kept his bed by Dr. Lapponi's advice, although all the symptoms (coryza, gravedo, febricula) had completely gone. Since Thursday last Dr. Lapponi has visited him three times daily instead of three times weekly, as is his ordinary custom, but the statements that the illness has been grave, necessitating Dr. Lapponi's spending entire nights at the Vatican, are wholly untrue. On the contrary, that exemplary consultant is not in the least alarmed at the condition of his Holiness whom he quite expects to be able next week to resume the suspended audiences—the reception of the clerical aristocracy and of the Princess of Sweden which had been fixed for Jan. 19th. One effect of these "statements on the best authority" or "announcements in well-informed circles" is greatly to add to Dr. Lapponi's occupation. Till two in the morning of yesterday he was incessantly called to the telephone to satisfy the representatives of foreign Powers and other diplomatic agents who importuned him for "information" confirming or contradicting the pessimistic paragraphs of the Continental journals.

The Academic "Insurrection."

The phrase is official and it appropriately describes the undergraduate mutiny and rioting of which the Universities of Palermo and Naples have just been the scene. At the former of these seats of learning the students, indignant at not getting their own way in the matter of examinations, "demonstrated" in characteristic fashion and from angry words proceeded to violent deeds, smashing the windows, the lamps, and the class-room furniture. At Naples the Sicilian outbreak had its replica and for some days his Excellency the Minister of Public Instruction (Dr. Baccelli) has been doing his utmost to restore order and induce a *modus vivendi* between the undergraduates and the professorial staff. He has not succeeded. On the contrary, he has had to issue a telegram sanctioning the temporary closure of these universities—a step taken by their Rectors and their Consiglio Academico. He further commands these authorities to announce publicly to the students that "they have lost the summer session examinations," and also to inform the young men's parents and guardians that if, on the reopening of the universities, the disturbances are renewed the entire academic year will be irrevocably sacrificed. He concludes by ordering the same authorities to assure the young men that as soon as the damage they have done to property has been ascertained they will be made to refund the equivalent in money under legal penalties. This is clear, direct admonition, and it ought to have the desired effect. But, unfortunately, the evil has its roots too deeply ramified in the Italian idiosyncrasy and academic [illegible] of its speedy or final extirpation. The whole undergraduate life in these southern nationalities is so different from the sober (or, as they consider it, sombre) English habits. The students (the bulk of them not much advanced in their teens) pose as precocious men, mix themselves up in contemporary politics, and seem bent on qualifying as future Cleons or Gracchi rather than as useful citizens in the professional sphere. They have the "mania contionabunda" developed prematurely, most of them being glib speakers or suffering from what Professor Pillans of Edinburgh used to call a "determination of words to the mouth." With such tastes and "distractions" they neglect their work and are continually demanding "extraordinary sessions" for "extraordinary examinations" to make up for their having let slip the opportunities open to them in the regular academic year. These demands have been so often conceded that they have come to be claimed as rights, to the prejudice of sound discipline and solid acquirement. Unfortunately, too, these precocious politicians have sympathisers in the Chamber of Deputies who aid and abet their young clients by making themselves troublesome to the Minister of Public Instruction for the time being, and so the wretched system tends to assume more formidable proportions from year to year. The lay press is alive to the serious consequences of this perversion of academic life and insists on a sterner vindication of authority on the part of the university heads. A beginning has just been made towards this consummation by his Excellency Dr. Baccelli's mandate to the Rectors and professorial staffs of the Neapolitan and Palermitan schools, and if the Cabinet to which he belongs holds together long enough—not a sanguine outlook in Italy any more than in France—he may be expected to work a salutary reform in his country's academic system.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Introduction of Bacilli of Bubonic Plague.

SOME months ago Dr. Leonard Haydon who was sent out to Bombay to the Plague Committee there and made investigations on plague bacilli arrived in Victoria on a visit to his brother. He brought with him several cultures of the bacilli. He showed his cultures to the President of the Board of Health and gave him information as to the measures taken in India to prevent the spread of the bubonic plague. When news came to Victoria of the fatal cases at Vienna from experiments with the plague bacilli at the *Pathological* Institute the Board of Health got alarmed and despatched its assistant medical officer with a detective to seize and destroy the bacilli in possession of Dr. Haydon. At first Dr. Haydon refused to give them up, pointing out that they were attenuated cultures and therefore not only harmless but that they would be of use in treatment should the disease reach the colony. He also claimed £300 as compensation if they were destroyed. Eventually, however, he handed them over and they were destroyed by heat. The Board had no legal power to seize the bacilli, but the Customs Act was brought in to aid on the ground that the gelatin of the cultures was dutiable and no duty had been paid. Dr. Haydon considers that he has been very unfairly treated, but the Board and the Government maintain that "the safety of the public is the supreme consideration." Dr. Haydon will probably receive compensation.

The Midwifery Nurses Bill (New South Wales).

On the Midwifery Nurses Bill coming up for its second reading in the New South Wales Legislative Council, after having been passed in the Assembly, the Attorney-General opposed the measure and said that the Government had received a communication from the Board of Health to the effect that the Bill imposed duties on the Board which could not be undertaken and were altogether outside the functions of that body. He said that the effect of the Bill would be to turn loose on the unthinking and undiscriminating public a class of women, really unqualified, but able to pose as qualified, and with a character almost as good as a medical man." The Bill was negatived by 27 votes to 4.

Poisons Act Amendment Bill (Victoria).

Reference has been previously made to the Poisons Act Amendment Bill introduced into the Legislative Assembly of Victoria. The Bill has now passed through all its stages in the Assembly and has been sent on to the Legislative Council. The Pharmacy Board desired some further amendments and restrictions which however were opposed by the medical societies as limiting the rights of medical practitioners in dispensing. In the discussion on the Bill in the Assembly the opinion was freely expressed that the Bill should make it compulsory for the composition of all patent medicines to be stated on the label, but the Bill was passed as drafted, the Chief Secretary promising to inquire into the effect of the proposed amendments.

Dentists Bill (Victoria).

A Bill to amend the law relating to dentists has been introduced in the Legislative Council of Victoria by the Government. It provides for a reduction in the number of members of the Dental Board from 7 to 6. 2 members are to be legally qualified medical practitioners and at least 3 are to be dentists. The board is to select examiners for conducting examinations and it may accept a certificate of examination in any particular subject by the University of Melbourne, the College of Pharmacy, or any school of mines or public educational institution. Unregistered persons are to be prohibited from using the name of "dentist," "dental surgeon," or "dental hospital," "college," or "school." Provision is made for registering dentists with recognised certificates obtained in other countries.

Annual Meeting of the Society of Medical Officers of Health (Victoria).

At the annual meeting of the Society of Medical Officers of Health of Victoria the election of officers resulted as follows:—President, Dr. J. Jamieson. Vice-Presidents, Dr. Courtney and Mr. Branson. Committee, Mr. Macmullen, Mr. Morton, Dr. Whitaker, and Dr. Gunst. Hon. sec. and treasurer, Dr. Daish. The report stated that the society had given special attention to the supply of pure drinking water in State schools; it claimed that it was obligatory on the Government to supply the children with pure air and pure water. The milk-supply had also specially engaged attention and the society had joined the other medical societies in a campaign against the present arrangements made compulsory by certain clauses in the Factories and Shops Act. The President then read a paper on Tuberculosis: its Prevention and Cure, and stated that about 800 persons died annually from that disease in Melbourne.

The Milk-Supply of Melbourne.

On the subject of the metropolitan milk supply a deputation of delegates from the Medical Society of Victoria, the Victorian Branch of the British Medical Association, the Melbourne Medical Association, and the Society of Health Officers, waited on the Chief Secretary to ask that the operation of the Factories and Shops Act with reference to the non-delivery of milk on Wednesday and Sunday afternoons should be suspended during the summer season. It was pointed out that under sections 45 and 46 of the Act it was illegal to deliver milk on two afternoons of the week. Diarrhœal complaints due to bad milk were responsible for 1000 out of 1600 deaths of infants in the metropolis. The Chief Secretary, in reply, said that the fault was in the whole system of milk-supply and the Act only legalised what had been the custom before it was passed and it did not prevent people going to the dairy for milk. The matter would receive his best attention and he would obtain a report on the subject from the Board of Health.

Tubercle in Meat in Victoria.

Some statistics recently prepared for the Minister of Agriculture in Victoria show that the number of cattle found to be affected with tubercle when slaughtered is very small as compared to other countries, being only ·4 per cent. as against 15 per cent. in Berlin, 17·7 per cent. in Denmark, 20 per cent. in France, 22 per cent. in Saxony, and 25 per cent. in England. This result is attributed to systematic inspection which is to be made still more rigorous.

The Medical Profession and the Friendly Societies.

Early in November a conference of delegates from the various medical societies in all the colonies was held in Melbourne to consider the relations between the profession and the friendly societies and endeavour to get some united and intercolonial action in remedying alleged abuses. The conference was summoned by the Medical Defence Association of Victoria and was attended by representatives from New South Wales and South Australia as well as from the country and metropolitan medical societies in Victoria. Queensland and Tasmania were unable to send delegates but were willing to coöperate. Mr. G. A. Syme was elected President of the conference and Dr. E. W. Anderson secretary. It was agreed that the present relations between the profession and the friendly societies were unsatisfactory and that the societies should impose a wage limit of £200 per annum upon all their members. It was also agreed that each member of a lodge should pay an annual fee of 10*s*. and a fee of 1*s*. for each consultation and 2*s*. 6*d*. for each visit of the lodge surgeon, and that midwifery and miscarriages, anæsthetics, accidents at sport, teeth extractions, operations, and cases involving legal proceedings should be extras. It was suggested that a conference be held between delegates from the meeting and delegates from the friendly societies. The Medical Defence Association issued a circular to its members asking for certain information, and from the replies it was apparent that the abuse of the lodge system by well-to-do persons was very prevalent.

Dec. 6th, 1898.

[*By Telegram.*]

Sir Alfred Roberts is dead.

Obituary.

JOSEPH COATS, M.D. GLASG.,

PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF GLASGOW.

IT is with much regret we announce the death of Dr. Joseph Coats, Professor of Pathology in the University of Glasgow and Pathologist to the Glasgow Western Infirmary. Dr. Coats had been in unsatisfactory health during the last two years. In the summer of 1897 he obtained leave of absence from his duties and spent some months in the Channel Islands. Subsequently he took a voyage to Australia and on his return was able for a time to conduct his class at the University. In the later months of last year his health again gave way, and more recently definite evidence of malignant disease appeared, and to this he succumbed at his residence in Glasgow on Jan. 24th. He leaves a widow and two daughters. Dr. Coats was a native of Paisley where he was born in 1846. He was educated at the Grammar School of that town and at the University of Glasgow It was at the latter institution that he pursued his medical studies and graduated with first class honours in 1867. He then proceeded to Germany where he spent two years, the greater part of the time being occupied in experimental work at Leipsic under Professor Ludwig. Shortly after his return to Glasgow he was appointed Pathologist to the Royal Infirmary and commenced to give a short course of lectures on pathology, a subject not then included in the official medical curriculum. He also gave considerable attention to the subject of diseases of the throat, and it may be remembered that he is responsible for the chapter on this subject in Dr Finlayson's Clinical Medicine. He very soon, however, concentrated his entire time and energies to pathological work, though it is noteworthy that he had had considerable experience as a hospital physician, and all his influence and teaching were strongly opposed to the view which would restrict the scope of pathology to the mere facts of post-mortem examination. On the contrary, he invariably led his students to regard the physiological and clinical relationships of these facts and to use their pathological studies as guides to a broad scientific and practical view of the nature and phenomena of disease.

When the Western Infirmary was opened Dr. Coats was appointed pathologist and his lectures were recognised by the University, but it was not until 1890 that he was appointed University lecturer and only in 1893 upon the foundation of the chair by the Universities' Commission that with universal approval he became Professor of Pathology and took his seat in the Senatus. But for fully twenty years before that date he had been the University professor in everything but name and many hundreds of students who are to-day mourning his untimely death are indebted to him not merely for technical instruction in the subject which he taught but for a steady example of earnestness, thoroughness, and loftiness of purpose and aim. The simplicity and strength of his character, his undeviating regard for accuracy in all the phases of human life, his fearlessness, and his earnestness of conviction were influences well appreciated both by his students and by all who knew him. Possibly to the stranger, and certainly to the trifler, a manner somewhat cold and reserved might seem to argue some deficiency of sympathy, but all associated with him knew him and trusted him as a just man, generous-hearted, unselfish, strong, and true.

The most considerable work which Dr. Coats presented to the profession was of course his "Manual of Pathology"; he also published together with his friend and colleague, Sir William Gairdner, a volume entitled, "Lectures on Tubercular Diseases." For many years he acted as Editor to the *Glasgow Medical Journal*, and numerous articles from his pen are to be found in the current literature of the last twenty years. His careful and exact powers of observation and the logical cast of his mind are well illustrated, for example, in the report of the Glasgow Commission on Anæsthetics and in an address on the nature of cancer which he delivered a few years ago as President of the Glasgow Medico-Chirurgical Society. His *alma mater* is indebted to him for many things, and the present position of pathology in the University is largely due to his influence. The splendidly equipped Pathological Institute now forming part of the resources of the University is a monument to his unflagging devotion and perseverance, whilst it is none the less true that his capacity for appreciating the aspirations and difficulties of younger men and his kindliness and guidance made his laboratory the scientific home of many earnest workers. The same personal qualities and the absolute confidence of his professional associates in his rectitude of purpose explain the active and responsible interest which he took in the establishment of the University Union and in all movements likely to promote the interests and welfare of young men. In all spheres and forms of professional activity it is not too much to say that he was held in the highest regard and was trusted, being known to be true. Dr. Coats was a man of deep and strong religious convictions. He was a member of the Baptist Church and for some years he acted as President of the Baptist Theological College in Scotland. No one can know a man like this and lose him without the consciousness of a severe and abiding wound.

HENRY ALLEYNE NICHOLSON, M.D., D.SC. EDIN., F.R.S.

DR. NICHOLSON, Regius Professor of Natural History in the University of Aberdeen, who died at his residence in that city on Jan. 19th, was born at Penrith, Cumberland. He received his early education at Appleby Grammar School, and afterwards commenced his scientific studies in the University of Gottingen. From 1862 to 1867 he studied medicine and the natural sciences at Edinburgh University, graduating M.B., C.M., in the latter year with first-class honours in all the subjects of examination and carrying off also the gold medal of the University for his thesis on the geology of his native county. In 1866, on obtaining the degree of B.Sc., he was awarded the Baxter Scholarship as the most distinguished science graduate of the year. In 1867 he graduated as D.Sc., and in 1869 on taking the degree of Doctor of Medicine he gained the Ettles Medical Scholarship as the most brilliant medical graduate of the year. During the next two years he was lecturer on natural history in the Extra-Academical School of Medicine, Edinburgh, and from 1871 to 1874 filled the chair of Natural History in the University of Toronto, Canada, making important researches during his stay in the Dominion. After two sessions' occupancy of the chair of Biology in the College of Physical Science in Newcastle in the home country, Dr. Nicholson was appointed Professor of Natural History in the University of St. Andrews, where he practically created the study of the subject and where he remained for six years. In 1877 he was chosen by the British Museum trustees as Swiney lecturer in Geology in succession to Dr. W. B. Carpenter, and he delivered four courses of lectures, partly palæontological and partly geological. In the beginning of May, 1882, he succeeded Professor Cossar Ewart in the Natural History chair at Aberdeen University, where he established an entirely new department of geology, both systematic and practical, and where he was up to within a few days of his death a most successful teacher. Dr. Nicholson was not only an accomplished lecturer, but was also a prolific author on geological and zoological subjects. Among his systematic treatises are "The Ancient Life History of the Earth" (1877) and "Manual of Palæontology" (1872—second edition in 1879). In 1897 he was elected a Fellow of the Royal Society of London. Dr. Nicholson was a thorough master of the subjects in his department and was very popular with the students and with his fellow professors, who feel that his death is a great loss to the University of Aberdeen. The funeral took place on Jan. 21st from the Mitchell Hall, Marischal College, and was largely attended by the members of the University Court and other academic bodies, the students, and the general public. Dr. Nicholson is survived by a widow, three sons, and two daughters.

JOHN DUNCAN, M.A., M.D., C.M. ABERD.

DR. JOHN DUNCAN died at his residence, Bideford, North Devon, on Jan. 13th, at the age of forty-two years. The deceased was a son of the Rev. J. Duncan of Aberdeen, and he received his education at the university of that town. He was awarded the Shepherd gold medal in surgery in 1884, and he graduated M.A., M.B., C.M. in 1885, taking the M.D. degree in 1895. He went to Bideford fourteen years ago as assistant to the late Dr. Cox, whose partner he shortly afterwards became, ultimately succeeding to the practice. Dr. Duncan, who was unmarried, was *greatly respected*, and much regret is felt in Bideford at his early death.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Preliminary Science Examination in Chemistry, Physics, and Practical Chemistry for the Diploma in Dental Surgery at the January meeting of the examiners, viz.:—

Mr. *Sydney Clifford, Birkbeck Literary and Scientific Institute; and* Mr. Robert Walker Craig, Wyggeston School, Leicester.

Two gentlemen were referred to their studies for three months.

The following arrangements for the lectures at the Royal College of Surgeons of England are announced: On Monday, Feb. 6th, Wednesday, Feb. 8th, and Friday, Feb. 10th, Professor Leonard E. Hill (Hunterian Professor) will deliver his lectures on "Researches on the Influence of Gravity on the Circulation." On Monday, Feb. 20th, Wednesday, Feb. 22nd, and Friday, Feb. 24th, Dr. T. Grigor Brodie will deliver the Erasmus Wilson lectures on "The Chemical Pathology of some Infective Diseases." Mr. Berkeley G. A. Moynihan will deliver the Arris and Gale lectures on Monday, Feb. 27th, Wednesday, March 1st, and Friday, March 3rd, on "The Anatomy and Surgery of the Peritoneal Fossæ." On Monday, March 6th, Wednesday, March 8th, and Friday, March 10th, *Professor Frederick G. Parsons* (Hunterian Professor) will lecture on "Joints of Mammals contrasted with those of Man." Professor Charles Stewart, F.R.S. (Hunterian Professor), will deliver six lectures on "*Alteration of Generation* and Recent Additions to the Museum" on Monday, March 13th, Wednesday, March 15th, Friday, March 17th, Monday, March 20th, Wednesday, March 22nd, and Friday, March 24th. The lectures will be delivered in the theatre of the College at 5 P.M. each day. The Hunterian Oration will be delivered on Tuesday, Feb. 14th, by Sir William Mac Cormac, Bart., K.C.V.O., President of the College, in the theatre of the College at 4 P.M. precisely.

SOCIETY OF APOTHECARIES OF LONDON.—In January the following candidates passed in the subjects indicated:—

Surgery.—F. M. Aldred, Liverpool; R. L. Argles, St. Mary's Hospital; H. H. Cotman (Section II.), Aberdeen and London Hospital; K. Grube, Bonn; R. R. Mowll (Section I.), King's College Hospital; A. Robinson, Leeds; S. Southam, Westminster Hospital; L. K. Tickner, Durham; H. Whittaker, *Cambridge; and* C. H. Williams, St. Bartholomew's Hospital.

Medicine.—R. B. P. S. Bowker, Middlesex Hospital; A. E. Freer, Edinburgh and St. Mary's Hospital; S. H. Longhurst, Guy's Hospital; D. V. Lowndes (Section II.), Westminster Hospital; G. S. Moore, London Hospital; and R. R. Mowll (Section I.), King's College Hospital.

Forensic Medicine.—R. R. P. S. Bowker, Middlesex Hospital; R. R. Mowll, King's College Hospital; and L. Liebster, Vienna and London Hospital.

Midwifery.—H. C. Cooper, St. George's Hospital; H. R. Cross, Leeds; H. Fawcett, Cambridge and London Hospital; E. J. Gruchy, London Hospital; W. M. McLoughlin, University College Hospital; C. G. Meade, St. Bartholomew's Hospital; and C. H. St. M. W. Toke and H. E. Weston, St. George's Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: Messrs. F. M. Aldred, R. L. Argles, H. H. Cotman, E. A. Gruchy, and A. Robinson.

THE INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.—At the January examinations the following candidates were successful:—

Practical Examination for the Associateship.—A. J. Chapman, F. E. P. Forster, and G. P. Lishman.

Intermediate Examination.—S. Aston, W. L. Blackman, B. R. Coysh, H. D. Hewitt, A. Hill, H. W. Kinnersley, J. Rogers, F. Shedden, and L. Wright.

Final Examination for the Associateship.—J. Golding, W. C. Hancock, A. Marshall, J. Imrie, R. Wild, W. S. Gilles, P. J. Hinks, T. F. Joyce, J. F. H. Gilbard, C. A. Hackman, and F. S. Young.

PAN-AMERICAN MEDICAL CONGRESS. — The Chicago *Railway Surgeon* of Nov. 29th, 1898, states that the Third Pan-American Medical Congress, which was appointed to be held in Caracas, Venezuela, in December, 1899, has been postponed on account of political troubles and an epidemic of small-pox and will be held in Caracas in December, 1900.

PRESENTATION TO A MEDICAL MAN. — On Jan. 16th Mr. Josiah Blomfield, M.D. Aberd., F.R.C.S. Eng., the medical officer of the Licensed Victuallers' Asylum, Old Kent-road, was the recipient from the inmates of that institution of an address handsomely illuminated on vellum, framed and glazed, as a testimony of his uniform kindness and medical skill to them and their predecessors during his fifty years of official service as medical officer. The presentation was made on behalf of the subscribers by Mr. Annett, the secretary of the asylum.

UNIVERSITY OF CAMBRIDGE. — On Jan. 19th the following medical degrees were conferred:—M.D.: E. A. R. Newman, B.A., Caius; M.B. and B.C.: C. R. Reissmann, B.A., St. John's; B.C.: E. C. Taylor, B.A., St. John's.—The contributions to the recently-established Benefaction Fund now amount to over £8500 and include £1000 from Lord Iveagh. A considerable number of the donations are for the rebuilding of the Medical School.—Mr. Strangeways-Pigg, Demonstrator of Pathology, who was conducting the classes during the vacancy of the professorship, has unfortunately fallen ill. His work will be carried on for the present by Dr. Drysdale, of St. Bartholomew's Hospital and St. John's College.

PRIZES OF THE PARIS ACADEMY OF SCIENCES.—The *Revue Scientifique* of Dec. 24th, 1898, publishes the awards of prizes made by the Paris Academy of Sciences and announced at the public annual meeting held on Dec. 19th. The prizes in medicine, surgery, and allied subjects were as follows:—Prix Montyon, of 7500 fr.: a prize of 2500 fr. was awarded to M. Widal for his researches on the Agglutinating Power of Serums; a prize of 2500 fr. was awarded to M. Bard for his works on Cellular Specificity; and a prize of 2500 fr. was divided between MM. Poncet and Bérard for their clinical treatise on Actinomycosis in the Human Subject. Prix Barbier, of 2000 fr., awarded to M. J. *Comby for his* Researches on Rickets. Prix Bréant, of 100,000 fr.: a prize the value of which was not stated was awarded to M. Phisalix for his Researches and *Discoveries* in Chemical Vaccines. Prix Godard, of 1000 fr., divided between M. B. Motz for a contribution to the Histology of Hypertrophy of the Prostate and M. F. Guiard *for* a Treatise on Blennorrhagia. Prix Bellion, of 1400 fr., awarded to M. Castaing for a memoir on the Ventilation of Buildings. Prix Mége, of *10,000 fr., divided between* MM. Labadie-Lagrave and Félix Legueu for their treatise on Medical and Surgical Gynæcology. Prix Lallemand, of 1800 fr., divided between Mr. Edward Phelps Allis for his memoir entitled "The Cranial Muscles and First Spinal Nerves of Amia Calva," and M. A. Thomas for a work on the Anatomy and Physiology of the Cerebellum. Prix Larrey, of 1000 fr., awarded to MM. J. Regnault and De Raoult for a work on the subject of Walking. Prix Montyon, of 750 fr., awarded to M. J. Tissot for a work on the Force Exercised by Muscle in Contracting. Prix Pourat, of 1400 fr., *for* investigation of the Motor Innervation of the Stomach, awarded to MM. D. Courtade and J. F. Guyon. Prix Philipeaux, of 890 fr., awarded to M. Moussu, for researches on the Functions of the Parathyroid Glands.

The Duchess of Albany opened a new Nurses' Home attached to the Chelsea Hospital for Women on Jan. 20th and subsequently paid a visit to the hospital.

Bristol Dispensary.—The annual meeting of the Bristol Dispensary was held on Jan. 13th. The medical report showed that 11,771 patients had been treated during 1898. The receipts amounted to £3124. The committee much regret the resignation of the honorary treasurer, Mr. F. J. Fry, who has been connected with the institution for the past forty-two years.

The Recovery of Medical Fees.—At the Barry County Court on Jan. 10th Mr. Patrick Kelly, L.R.C.P. Edin., L.R.C.S. Irel., sued a man for £4 10*s.* for medical attendance. Owing to the nature of the case Mr. Kelly would not give full particulars in court and as he also had not supplied them to the defendant the judge adjourned the case for a month in order that he might do so, ordering Mr. Kelly to pay the costs of the day.

Diamond Jubilee Memorial at Margate.—The enlargement of the Cottage Hospital at Margate which was undertaken in commemoration of Her Majesty's Diamond Jubilee upon the suggestion of Mr. Bertram Thornton, has recently been in progress, and on Thursday, Jan. 19th, the new central block of the hospital was opened by the Right Hon. James Lowther. The original "cottage" which formed the nucleus of the institution has been entirely pulled down, leaving the added Lucas and Wilcox wards and the operating room. On the vacant site and part of the front garden a large building has been erected, with all the requirements of a modern hospital.

Bradford and District Medico-Ethical Society.—The annual general meeting of this society was held on Jan. 18th at the Midland Hotel, Bradford. There was a large attendance, the following gentlemen being present: Dr. C. F. M. Althorp, Dr. S. Johnston, Mr. I. Mossop, Mr. E. G. Peck, Dr. R. Hamilton, Mr. P. E. Miall, Dr. Bell Graham, Dr. T. C. Denby, Dr. W. Horrocks, Dr. J. H. Bell, Dr. F. W. Eurich, Dr. W. A. Evans, Dr. D. Goyder, Mr. W. J. Parkinson, Dr. A. Manknell, Dr. F. K. March, Mr. H. J. Butler, Mr. R. Love, Dr. T. Jason Wood, Dr. B. Hall, Dr. A. Rabagliati, Dr. A. Bronner, Mr. G. H. Moorhead, and Mr. W. Handcock. The usual business of the society was transacted and the following is a list of the officers elected for the ensuing year:—President: Mr. P. E. Miall. Vice-President: Dr. T. C. Denby. Treasurer: Dr. F. K. March. Secretaries: Dr. W. Horrocks and Dr. A. Manknell. Committee: Dr. C. F. M. Althorp, Dr. D. Goyder, Dr. J. H. Bell, Mr. I. Mossop, Dr. A. Rabagliati, and Mr. H. J. Butler. Auditors: Mr. W. J. Parkinson and Mr. E. G. Peck.

Literary Intelligence.—Messrs. Williams and Norgate's book circular for December, 1898, announces the early appearance of the following medical and surgical works: vol. xxviii. of the "Jahresbericht über die Leistungen und Fortschritte auf dem Gebiete der Ophthalmologie"; vol. ii. of the "Traité de Microbiologie," by Duclaux (vol. i. was issued in the early part of 1898); vol. i., for the year 1897, of the "Jahresbericht über die Leistungen und Fortschritte auf dem Gebiete der Neurologie und Psychiatrie," edited by Professor E. Mendel, Dr. L. Flatau, and Dr. L. Jacobson; a second and enlarged edition of the "Atlas des Menschlichen Gehirns und des Faserverlaufes," by Dr. Edward Flatau of Berlin; "Experimentelle Studien über die Fettgewebsnekrose des Pankreas," by Dr. A. Katz and Dr. F. Winkler of Vienna; "Anleitung zur Uebungs-behandlung der Ataxie," by Professor A. Goldscheider. The forthcoming part of the "Beiträge zur Klinischen Chirurgie" will contain an illustrated article on the Dum-Dum Bullet and its Effect on the Human Body by Professor von Bruns who has already written on the subject.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1898, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 6*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

◆

THE HUMOURS OF SCHOOL INSPECTION.

WE always suspect the funny answers at examinations which we now and again read in the press of having been concocted, but the paper in the current *Cornhill* from the pen of a school inspector appears to be a record of actual experiences. Science, as usual, comes off badly: "The equator is an imaginary line going round the earth once in every twenty four hours," and medicine even worse: "The diaphragm is a *serious* petition between the thorax and the abdominal regions;" "The bowels are five in number—a, e, i, o, and u;" "Oxygen, hydrogen, and a little carbon is the best food for infants."

Communications, Letters, &c., have been received from—

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières Paris.

ABSTRACT OF

An Address

ON

THE PREVENTION OF PHTHISIS, WITH SPECIAL REFERENCE TO ITS NOTIFICATION TO THE MEDICAL OFFICER OF HEALTH

Being an Introduction to a Discussion on the Subject at a Meeting of the Incorporated Society of Medical Officers of Health on Jan 13th 1899,

By ARTHUR NEWSHOLME, M D,
F R C P LOND,
MEDICAL OFFICER OF HEALTH OF BRIGHTON EXAMINER IN STATE AND PREVENTIVE MEDICINE TO THE UNIVERSITIES OF LONDON AND OXFORD

NATURE OF TUBERCULOSIS

GENTLEMEN,—Our views as to tuberculosis have been fundamentally changed by the discovery of Koch s bacillus tuberculosis Tuberculosis having been shown to be an infective disease it is natural to jump to the conclusion that it is spread by direct or indirect personal infection This is not necessarily the case Tetanus is an infective disease the contagion of which is widely present in the soil but it is not communicable except under the most unusual conditions Rheumatic fever, again, is an infective disease which is ordinarily non-communicable The evidence of such pioneers as Cornet, Niven, and Ransome and the gradually accumulating evidence of other observers makes it quite clear that under certain conditions phthisis is actively infective

The following cases taken from my annual report for 1894 are illustrations of similar facts which although they may singly be explained as coincidences force one to the conclusion that infection is at work when we remember that similar cases occur time after time in particular houses among members of different families

A woman aged 40 years, died from phthisis She had been married twice both husbands having died before her from phthisis The history indicated that she had probably acquired the disease from her first husband and had given it to her second husband in whom it ran a more rapid course than in herself

A man aged 47 years died from phthisis in October 1894 after an illness of several years His daughter who helped to nurse him died in January 1894 from phthisis

On Jan 19th 1894 a boy aged eight years died from phthisis a sister having succumbed to the same disease in December 1891 On Jan 14th 1894 a lodger s child aged 12 months, who had lived in the house since his birth died from tuberculous meningitis.

We need in the next place to differentiate between diseases which are infective to all and diseases which are infective only to a minority Tuberculosis undoubtedly comes under the latter category The difference in incidence of infection between tuberculosis and such diseases—such as diphtheria enteric fever, and scarlet fever—is simply one of degree In my own family there has been a complete immunity from scarlet fever of every member during three generations notwithstanding frequent exposures to the disease

It is true, as urged by the late Professor Kanthack, that a preponderant proportion of the population enjoy immunity from phthisis, but an appeal to pathological anatomy shows that a very large proportion of the population dying from other diseases has in the lungs what may be described as the scars resulting from a successful fight against phthisis while the national statistics show that between the ages of 15 and 55 years more than one fourth of the total deaths from all causes are due to phthisis no account being taken of other tuberculous diseases We must set against the fact that phthisis is infective to a minority of the population only the fact that it is infective for a prolonged period The lesser intensity of infection is probably more than counterbalanced by its longer duration The breath of the phthisical patient being free from infection it is evident that in seeking for means of preventing the disease we must have regard to (1) the infectious discharges from the patient, especially his desiccated sputa and (2) the personal and environmental circumstances which favour the origin of phthisis

If we assume for a moment that the contagion of phthisis has no extra corporeal existence it is evident that we might faintly hope to annihilate the disease by strictly isolating all phthisical patients and destroying their discharges, though our experience of such diseases as small pox (apart from vaccination) would sober any too sanguine expectations In practice segregation of the phthisical patient, except where it is voluntarily undertaken in the interest of the patient, is entirely out of the question Voluntary isolation may be recommended in two directions:—

1 Of the patient himself when the home conditions are unfavourable to his recovery with a view to securing his cure in a well-organised sanatorium

2. The relatives who are particularly prone to fall victims may be removed from the home in which the patient is being treated or has been treated with a great increase of the probability of their escape from the family disease.

It is well to recognise the fact that before phthisis is diagnosed the patient has commonly been expectorating myriads of tubercle bacilli and that consequently attempts to destroy infective material derived from the patient can have only a partial and limited success This consideration has been urged as the standard argument against notification of cases of phthisis and the precautionary measures which would follow as the result of such notification Such reasoning is somewhat short sighted The healthy occupants of a phthisical home may be compared to a city which is the subject of a protracted siege in which the combined effects of arms, starvation, and depressing emotion are at work The inhabitants of such a city may escape with but little damage if the siege is raised at a comparatively early period, but they succumb if it is protracted Similarly the healthy members of a phthisically invaded household may be able to withstand infection if precautionary measures are begun as soon as the nature of the disease is detected and are continued thereafter, but they finally fall victims to the repeated doses of infection if a fatalistic inertia is allowed to prevail and no efficient precautions are taken

THE SAPROPHYTIC QUESTION

The question of the possible saprophytism of the tubercle bacillus raises another range of difficulties Ransome and others have shown that the tubercle bacillus can live on artificial media and even on wall papers at the ordinary temperature of certain rooms This being so and there being presumably a large stock of tubercle bacilli in progress of development in the incubating chambers of nature, why trouble to destroy the tubercle bacilli discharged by each patient? We may, however, reasonably doubt the saprophytism of the tubercle bacillus except to the limited extent that it manages to retain a slender tenure of life under certain extremely favourable extra corporeal conditions The evidence of protracted saprophytism in diphtheria and enteric fever (and I believe also in scarlet fever) is much stronger than in the case of tuberculosis And yet, although the saprophytic stage of life of the contagia of diphtheria and enteric fever indefinitely multiplies their possibilities of infectivity these diseases remain compulsorily notifiable, nor do I anticipate that the Local Government Board will recommend their removal from the list of diseases thus notifiable

[Dr Newsholme then pointed out that the saprophytic bogie idea was likely to do much mischief unless relegated to its proper place Contagion was really the source of trouble and hygienic measures must be directed towards cleanliness light, ventilation, and against damp and access of ground air]

It remains true, however, that the prevention of phthisis is concerned largely if not chiefly with the personal and environmental conditions which favour its origin Now what are the chief predisposing causes of phthisis? Without attempting an exhaustive enumeration the following are probably the most important (1) the habitual breathing of re-breathed air, (2) dusty occupations, (3) dampness and darkness of the dwelling, and (4) chronic alcoholism The prevention of alcoholism is outside the ordinary scope of preventive medicine Its importance, however, deserves a passing notice

SANITARY AUTHORITIES AND PREVENTIVE MEASURES

It will be argued that sanitary authorities (local or central) already have power under existing laws to diminish the operation of respiratory impurities and industrial dust and, possibly to a less extent of damp and dark houses That is a plausible opinion which will probably continue to find favour with those who have no practical experience of local sanitary administration, but it will not bear critical study. Even supposing that there are ample legal enactments against overcrowding and dust it must be admitted that the knowledge of a case of phthisis in connexion with overcrowding or a dusty occupation will enormously strengthen our hands in securing the adoption of the necessary remedies. Many nuisances cannot now in many districts be remedied because support is not obtained from the sanitary authority or the magisterial bench. Would not a medical certificate that a case of phthisis had occurred in the house where the nuisance was found turn the balance in favour of reform?

It is not true, however, that present enactments cover the entire requirements of the case. The knowledge of cases of phthisis would give immense leverage in securing the removal of conditions of defective sanitation which we know to favour phthisis but which *cannot at present* be reached except by judicious persuasion. Take, for instance, the question of enforcing the provision of a staircase window where none now exists and where its absence means blocking of what ought to be the main channel of air and light to the house. In Brighton we have during 1898 secured the insertion of such staircase windows in 126 houses which were previously without them and 81 are now under notice but it would have been extremely difficult to enforce these notices had they been contested. Similar remarks will apply to the enforcement of damp-preventing structural alterations, of windows which can be opened top and bottom, and other arrangements for ventilation, and of notices to remove and destroy wall-papers in rooms where a case of phthisis has been nursed for a long time. It will be argued that information as to the above and allied defects could be obtained apart from notification of cases of phthisis in the course of the house-to-house inspection which is carried out in the majority of districts. This statement implies deficient knowledge of the conditions under which these visits are made. Even in well-organised districts a house is seldom inspected oftener than once a year and it must be evident that if we knew of a case of phthisis in a house immediate cognisance could be taken of and action adopted in respect of conditions favouring phthisis which under other circumstances would probably be delayed for many months and which might have to be entirely omitted in the present state of the education of the public. Our leverage in sanitary operations would be enormously increased if a considerable proportion of the cases of phthisis were notified. Quite apart from the adoption of special precautionary measures against infection the localisation and remedying of house defects as to cleanliness, crowding, and dampness would amply repay for all attempts at the notification of phthisis.

NOTIFICATION OF PHTHISIS.

It being obvious that a more complete knowledge of cases of phthisis would enable more complete preventive measures to be adopted it is not surprising that a number of local sanitary authorities have written to the Local Government Board for permission to add phthisis to the list of notifiable diseases. They have received the following reply which has already been made public property:—

> Local Government Board, Whitehall, S.W.
>
> To the Clerk to the District Council.
>
> SIR,—I am directed by the Local Government Board to advert to your letter of the ......, inquiring whether they would approve an Order extending the provisions of the Infectious Disease (Notification) Act, 1889, to phthisis in the .... District.
>
> In reply I am to state that the Board have hitherto held the view that phthisis is not a disease to which the provisions of the above-mentioned Act could with advantage be applied and in this connexion I am to remind the District Council that many persons who would be notified to them as suffering from phthisis would be individuals whose phthisis is so little advanced that not a few of them may be expected to have many years of life in prospect, during which it will be imperative on them to gain their livelihood. I am to add that the Board do not find in the medical officer of health's report which accompanied your letter any evidence to cause them to modify that view. They therefore would not be willing to approve of the addition of phthisis to the list of diseases notifiable in the .... District under the Act.
>
> I am,
>
> ....
>
> Assistant Secretary.

It is evident from this letter that one of the chief arguments against a compulsory notification of phthisis is held to be the risk of interfering with the means of livelihood of phthisical patients. The same argument is stated in Sir Richard Thorne's Harben Lectures.[1] "It was not desirable that persons suffering from phthisis should occupy the *same* rooms as the healthy, but the notification of such cases in houses of business would be followed by dismissal." The two halves of this sentence are mutually destructive, but that doubtless is owing to the briefness of the abstract. Notification of disease is confidential and if the Local Government Board are afraid of its misuse they can make regulations bearing on this point. The inquiries resulting from notification would in nearly every instance be made at the patient's home, not at his place of business, and with proper provisions there need be (and would be) no interference with business. In the final analysis, if any must suffer, ought it not to be one rather than many? But I repeat that there is not the slightest necessity for anyone to suffer through notification and the medical officer of health through whose action such suffering arose would *speedily find his position so uncomfortable that* the indiscretion would not be repeated.[2]

Then it is stated in the abstract of the lectures above quoted that "notification of phthisis is impracticable and would tend in its results to defeat the end in view." The diseases at present notifiable "were communicable in a high degree and in many ways, but rendered the patient a source of danger for a limited period only. In phthisis not only were these conditions absent, but the patient's position was absolutely the reverse." Thus because the danger in scarlet fever is for a limited period only we must take every possible precaution against it, but the danger of phthisis being protracted we must trust to the casual precautions which the uninstructed patient or the overworked practitioner may carry out on his own initiative. Personally I should be prepared to leave the precautionary measures almost entirely to the medical attendant and his patient, with the stipulation that as medical officer of health I should be informed of each change of address of the patient in order to secure the protection of subsequent tenants of the vacated house. But it is not simply or chiefly a question of personal precautions. The above argument entirely ignores the sanitary aspect of the question. Inspections and control of the home conditions and of the industrial conditions under which phthisis has originated are of the very essence of the means of preventing phthisis. How can we exercise such control when we do not know of a tithe of the total cases and of these only when they prove fatal? The last Factory and Workshops Act contains a clause securing the compulsory notification of anthrax, phosphorus and arsenical poisoning, and of a chronic disease like lead-poisoning *occurring* in connexion with industries. Each of these has an annual number of victims who could almost be counted on the fingers, while thousands of the artisans of this country annually fall victims to phthisis acquired in connexion with their special work. But lead-poisoning must be notified; phthisis is ignored. The non-communicable disease must be notified; the communicable disease is left to carry out its maleficent work. Then we are told above that fevers are "communicable in a high degree and in many ways." Enteric fever, a notifiable disease, is spread almost solely by infection from the dejecta of previous enteric patients; phthisis by the dried sputa of phthisical patients. But there is the "less degree" of infectivity in the latter case. It would be an interesting arithmetical problem to find the sum total of infectivity (call it a) in the month's course of attack of enteric fever and in the from two to three years' average course of phthisis (call it b) when it pursues a fatal course. It is clear, I think, that if x represented the unknown balance on one side of the equation, probably a very large one, it would stand as follows:—

$$a + x = b.$$

Then it is stated: "A little reflection would show the impracticability of carrying out such a course of repeated visitation of hundreds and thousands of houses in large sanitary districts, where already it was found impossible for the medical officer of health to visit all the cases now notified."

---

[1] Summary in Public Health, December, 1898, p. 205.

[2] While writing the above I have heard of the case of a clerk who appears to have been discharged from his post because he was phthisical in connexion with the publicity recently given to the dangers arising from the sputa of such patients. If the admirable propagandism of the Association for the Prevention of Tuberculosis is to continue (and we all hope that it will) a certain amount of alarm among those imperfectly informed is inevitable. In all probability nothing would be more successful in removing this unreasonable fear—unreasonable when proper precautions are taken—than the knowledge that cases of phthisis are notified to the medical officer of health who has official charge of any necessarily precautionary measures.

It may be remarked that personal visits by the medical officer of health are not required in every case to ensure the execution of the necessary sanitary improvements and hygienic precautions. The head of a large firm does not conduct every detailed operation in his business, otherwise he would be his own clerk and messenger. But he has full control of the business; he knows its weak points and its strong points and is able to maintain control over its minutest details. Assuming that in a well-organised district each house is inspected at least once in every twelve months we ask, Is it not very desirable that the visits of a large sanitary staff shall be made once in three or four months to a minority of houses in which remedial measures against dirty rooms, overcrowding, damp, and deficient ventilation are of supreme importance, even though this may necessitate a less frequent inspection than once a year of houses the absence of phthisis from which makes such inspections less urgent? Speaking from fifteen years' experience of local sanitary administration in London and in Brighton I have no hesitation in stating my emphatic opinion that the visitation of phthisical houses in which such visits are desirable is not only perfectly practicable, but is of as great importance to the public weal as similar visits in houses where diphtheria or enteric fever has occurred. I protest against the assumption which appears to be so commonly entertained that the official work of the medical officer of health is confined to the "seven chief zymotic diseases" and that tuberculous diseases which cause 50 per cent. more deaths than the aggregate of these seven zymotic diseases and are much more capable of being prevented than are several of them are outside the sphere of his official action. Then we are informed, I hope under some misapprehension, that a distinguished physician has maintained that "the question revolves itself into that of the disposal of the sputa" and has asked "what the sanitary authority would do with the patient when notified." The answer is that so far as the patient is concerned notification need imply, and ought to imply, until experience has shown that more is really necessary, nothing beyond sending to him a precautionary circular such as the following which is used in Brighton:—

PRECAUTIONS FOR CONSUMPTIVE PERSONS.

Consumption is to a limited extent a contagious disease. It is spread chiefly by inhaling the expectoration (spit) of patients which has been allowed to become dry and float about the room as dust.

Do not spit except into receptacles the contents of which can be destroyed before they become dry

If this simple precaution is taken there is practically no danger of infection The breath of consumptive persons is free from infection.

The following detailed rules will be found useful both to the consumptive and to his friends:—

1. Expectoration indoors should be received into small paper bags and afterwards burnt.
2. Expectoration out-of-doors should be received into a suitable bottle, to be afterwards washed out with boiling water, or into a small paper handkerchief which is afterwards burnt
3. If ordinary handkerchiefs are ever used for expectoration they should be put into boiling water before they have time to become dry or into some disinfectant solution to be ordered by the doctor
4 Wet cleansing of rooms, particularly of bedrooms *occupied* by sick persons, should be substituted for "dusting.".
5. Sunlight and fresh air are the greatest enemies of infection. Every consumptive should sleep with his bedroom window open top and bottom and during the day should occupy a well-ventilated room. Re-breathed air is the main cause favouring consumption. If the patient is warmly clad he need not fear keeping out-of-doors in any weather. N.B.—The patient himself is the greatest gainer by the above precautions as his recovery is retarded and frequently prevented by renewed infection derived from his own expectoration.
6. Persons in good health have no reason to fear the infection of consumption. Over-fatigue, intemperance, bad air, and dusty occupations favour consumption.

HOW NOTIFICATION MAY BE LIMITED.

This is all so far as the patient is concerned. If there is any fear on this point effectual legal safeguards can be devised, and I may point out that notification may be compulsorily adopted and its operation limited by Section 58 of the Public Health (London) Act, 1891, to special purposes. It is not all so far as the prevention of phthisis is concerned. The weightier matters of the prevention of phthisis deal with the home and industrial evils which have lowered vitality to such an extent that a dose of infective material which to the healthy would be innocuous has been enabled to secure a foothold and multiply in the patient's lungs. It is unfortunate that the Local Government Board is so unacquainted with local requirements that it has hitherto been unable to entertain the idea of modifications of compulsory notification and of fresh legislation if necessary giving notification for certain purposes of a strictly restricted character. I hope that ere long some local authority will apply to the Local Government Board for permission to enable them to pay practitioners for voluntary notifications of cases of phthisis supplied to them. Such voluntary notification would supply information of the cases of phthisis among the poor which are most important from a preventive standpoint. Nor is there the same objection to paying for a limited notification of phthisis that would hold for such a disease as enteric fever. The absence of complete information in a limited outbreak of enteric fever may prevent one from discovering its origin; but in phthisis every single case notified may be treated alone, and if 25 per cent. of the total cases in a district are notified we can obtain nearly if not quite 25 per cent. of the benefit which would follow in the wake of complete notification. As matters now stand any district or borough other than a county borough which paid fees for such voluntary notification would probably find the accounts disallowed by the Government auditor. It may be asked, why not be contented with the voluntary notification of phthisis? Personally I am at present satisfied with such voluntary notification, which is being made to me by medical officers of public hospitals and dispensaries and by parochial medical officers. It is, however, a hardship that they apparently cannot be paid a fee as in the case of notification of other diseases. I draw attention in this connexion to the resolution passed unanimously at the annual provincial meeting of the Society of Medical Officers of Health at Newcastle-on-Tyne in 1893:—

> That the Society of Medical Officers of Health, while accepting the view that phthisis in an infective disease, in the prevention of which active hygienic measures should be taken, think it premature to recommend the compulsory notification of a chronic disease like phthisis. They are, however, of opinion that it is incumbent on medical officers of health to take such steps as may secure (*a*) the voluntary notification of cases of phthisis by medical officers of public institutions and such medical practitioners as agree that precautionary measures are desirable; (*b*) the adoption of such precautionary measures, including the disinfection of rooms, as can be arranged in conjunction with the family practitioner. For this purpose the memorandum prepared by the North-West Branch of the Incorporated Society of Medical Officers of Health would give an excellent basis of action.

I was responsible for drafting and proposing the above resolution and am contented to continue to act upon it for the present subject to phthisis being placed in the same category as other infective diseases so far as payment for certification is concerned. I venture, however, to protest against the obstructive action of the Local Government Board in not allowing such local authorities as wish for it to adopt the compulsory notification of phthisis. There should be complete local option in this respect and it is only by experiment that progress can be secured. This is not the only respect in which the Local Government Board has *effectively* obstructed local authorities, especially the local authorities of great towns, in their attempts to improve their sanitary enactments and administration. In former years they were content to stand neutral while the great towns secured special enactments of their own, and they subsequently adopted many of these enactments permissively in the Infectious Disease Prevention Act and the Public Health Amendment Act. Latterly they not only refuse to move themselves, but insist on everyone else sitting still. Their action is unfortunate, as the prospects of local sanitary progress at present depend upon the assent if not the cooperation of the Local Government Board. I would heartily increase the present powers of the Local Government Board, which they allow to a very large extent to remain in abeyance, for compelling local authorities to do their duty, but at the same time their power of veto on local authorities who are laudably anxious to extend their responsibilities and their utility should be removed.

It may be inquired, in conclusion, what can be done apart from compulsory notification of phthisis? Dr. Niven and Mr. C. E. Paget (and others) have made serious attempts with the machinery already available and I take this opportunity of acknowledging the magnificent pioneer work of an educational and actively preventive character which they and Dr. Ransome have done. Mr. Paget informs me, however, that during the five years 1893–97 in which voluntary disinfection after phthisis was offered in Salford only 32 houses were thus purified. We are told that one item of the programme of the Association for the Prevention of Consumption is to secure the disinfection of houses in which deaths from phthisis have occurred. The association is apparently unaware in how many towns this is already carried out. The number of rooms cleansed and purified in after deaths from phthisis has been as follows:—

Year.	No. of rooms.	Year.	No. of rooms.
1893...	56	1897...	138
1894...	64	1898...	108
1895...	57		—
1896...	150	*Total in six years*	573

The procedure is that a copy of a circular is sent by post as soon as the weekly death returns come in to the head of the household in which the death has occurred and a visit is made during the week to ensure that the work has been carried out. This has been recently supplemented by a system of voluntary notification of all cases of phthisis removed to the workhouse, the house vacated by the patient being similarly purified. The recommendations of this circular are shortly as follows:—

1. Strip the wall paper off the wall. The paper should afterwards be burnt in the fireplace of the same room.

N.B.—The chief danger is from dust. Hence all articles should be thoroughly wetted before cleansing them. A supply of disinfectant for mixing with the water can be obtained free of cost at the office at the town hall, *but a disinfectant is not essential if everything is thoroughly wetted.*

2. Thoroughly wash the ceilings and floors and walls of the room.

3. Wash all bed-linen and other articles in the room and expose all bedding, pillows, &c., out of doors for several hours in bright sunshine.

For the last five years every death from any form of tuberculous disease has been made the subject of an inquiry under the following heads:—

Deaths from tubercular diseases.—Sex, age, disease, address, name of doctor, date of death, duration of illness, source of milk supply, places of residence during illness, nature of occupation during the last ten years, other cases of allied disease in the family, previous history of the house.

Condition of the house as regards (1) overcrowding, number of occupants (over 10, under 10), number of living rooms and bedrooms; (2) whether animals kept; (3) condition as to dampness, condition as to cleanliness; (4) ventilation; (5) lighting; (6) drainage arrangements; (7) dustbin; (8) size of yard, condition of paving.

I have omitted from my purview tuberculosis derived from the ingesta. The growth of public opinion as to the tuberculin test for cows and as to the provision of public abattoirs is so satisfactory that there is little doubt that valid progress will be made in these respects. I am anxious to confine our attention to the one question of notification of phthisis. I trust that we shall not allow small difficulties of detail to embarrass us. (The question of multiple notifications, for instance, is a very minor matter which can be safeguarded if necessary. Dr. Niven has shown, however, that there is practically no need for this.) If notification is desirable in the interests of the public health it should be adopted and a desirable principle is never impracticable. If limits of official action after notification are desirable there will be no difficulty in devising the scope of these limitations. We have heard so much about the reduction in the mortality from phthisis that the unthinking may lose sight of the enormous mortality still caused by it. Had time permitted I should like to have drawn attention to the erroneous inferences which have been drawn or suggested as arising out of the reduction of tuberculous diseases in adults along with the increased consumption of meat and the stationary mortality from tabes mesenterica along with the infantile use of cow's milk as food, but that must be reserved for another opportunity. I beg finally to recommend to your consideration the desirability of making representations to the Local Government Board urging upon the Board the importance of: 1. Allowing the same local option in respect of the notification of phthisis as of diseases which they at present allow to be added to the schedule of notifiable diseases. 2. Giving powers to local authorities to pay fees for voluntary notification of cases of phthisis. 3. Bringing up to date and codifying other sanitary legislation which has an important bearing on the *prevention of phthisis—e.g., further* precautions against encroachment on open spaces at the rear of dwellings,[3] enactments compelling local authorities to adopt proper by-laws for the erection of new buildings, improvements of the Housing of the Working Classes Act, &c.

A Clinical Lecture

AND DEMONSTRATION ON

LOCAL INFILTRATION ANALGESIA.

Delivered at University College Hospital on Jan. 19th, 1899,

By ARTHUR E. BARKER, F.R.C.S. ENG.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AND PROFESSOR OF CLINICAL SURGERY AT UNIVERSITY COLLEGE, AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—For the last eight or nine months I have occasionally been operating on patients for various surgical conditions without using either chloroform or ether, trusting rather to one or other form of "local infiltration analgesia." Several of these cases have, as some of you have seen quite lately, shown such remarkable results as to afford much food for reflection. During all this period I have been endeavouring to make myself familiar with the whole subject of infiltration analgesia by every means in my power. Having seen the method employed abroad where it is largely used and having been much impressed by it it was only rational to get hold of the best and most recent of the now very numerous monographs on the subject and to study them carefully both as regards the physiological and physical theories advanced and the details of the practical application of the latter advocated in them. I confess for myself that I have only recently felt the full importance of the whole subject, though the study of it has been long. This is probably due to the fact that the mere manipulative details of the procedure, without the proper accomplishment of which analgesia is not produced, require considerable practice for their mastery and that at the outset one naturally only employs a new method in carefully selected cases. But of late these have increased in number and I can now claim to have familiarised myself with the procedure sufficiently to have approached the results in even long and serious operations which have already been achieved on a larger scale abroad, and the results I propose now to put before you. If you are at all like myself you will feel for a time a certain amount of distrust of the method and incredulity as to the results claimed for it here and there, but equally if you study the matter fairly you will be forced in the end to the conclusion, as I myself have been, that there is a great deal in "local infiltration analgesia" when properly carried out and that the results claimed for it by those who have employed it in hundreds of cases have not been exaggerated. But that to utilise it safely and extensively demands close study of the procedure on the widest basis is every day more and more clear to me and I hope will become so to you if you listen to my remarks and watch the operations to follow in which I hope to demonstrate the method in question.

To anyone who gives close attention to the practical details of local analgesia induced by the endermic injection of cocaine or eucaine β it must soon become abundantly evident that the procedure does not consist in the mere injection of a certain amount of one or other drug, so to speak, at haphazard into the field of operation. Many factors require to be taken into very careful consideration if we are to approach at all near to the end which we have in view—namely, the safe abolition of pain without the use of general anæsthetics such as chloroform, ether, &c.

When cocaine was first brought to the notice of surgeons many years ago great expectations were entertained as to its application to minor surgery. But experience with the stronger solutions of the drug (which were then considered necessary) soon proved, first, that it was dangerous and, next, that its action as then used in strong solutions was too local for anything but the most limited employment. It was therefore reserved for superficial parts, such as the eye, the mouth, and the anus almost exclusively. And I can well remember how disappointed I was myself in using it 12 or 15 years ago in cases of piles and on the gums and nose. Since then, however, important modifications have been made in the manner of employing these drugs which have led to their widespread use even for some of the greatest operations in surgery.

The primal fact which we have to keep in mind is that cocaine and its salts applied to the trunk of a *sensory nerve* suspend the functions of the latter and abolish the sense of pain in all parts supplied by its terminal ramifications.

---

[3] Among the most serious defects of the present law are the following: (*a*) In accordance with the model building by-laws a certain amount of free air space must be allowed at the rear of every dwelling-house. If, however, a person erects a building in his back yard encroaching on this air space and the encroachment is not discovered within six (or under certain possible but exceptional conditions twelve) months from the time of its erection the encroaching building cannot be compelled to be removed. (*b*) In the case of dwellings erected prior to the adoption of any building by-laws it is no offence to erect other buildings upon the open space attached to the *old buildings*, subject to the new buildings themselves *fulfilling the requirements of* the by-laws as to open space. The result of the defects of the law in the above respects is that insanitary areas, the fit breeding place for phthisis, are being produced in nearly every town, particularly in their more central parts.

The first who appears to have made practical use of this fact (which had been published in 1885 in America by Corning and in the same year in Russia by Feinberg, independently of one another) was the French surgeon Reclus, whose method of producing analgesia by the injection of 1 per cent. cocaine solutions into the soft parts layer by layer does not differ in principle from the methods since developed and may be taken as the beginning of what is now known as "local infiltration analgesia." But it was found that even with such a dilute solution as that used by Reclus (= 1 per cent) toxic effects followed in a few cases and that the application of his method had consequently to be limited to very small operations—that is, to operations confined to a small area. But in carrying out the principles underlying Reclus's method Schleich was able by further reducing the concentration of the cocaine solution and by using much greater quantities to extend the method to very much more wide-reaching operations, until now among adult patients it is employed very largely. It appears to me therefore proper that due credit should be given to Schleich for having, as it were, popularised this proceeding by reducing its risks and extending its use, although many of his data and theoretical conclusions were apparently erroneous.

But numerous modifications of Schleich's method also have been made since then in many directions and it has been simplified and improved. One of these improvements introduced by Oberst but foreshadowed by Corning is only applicable so far to the fingers and toes and perhaps to the whole hand and foot. It consists in arresting the return of blood from a member by applying an elastic ligature round its root and then injecting a very moderate amount of the cocaine solution over each of the several nerves of the part.

FIG. 1.

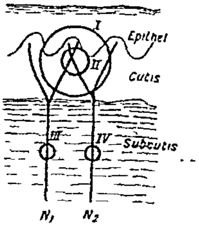

Diagram illustrating field of action of an injection according to the site selected.

This arrest of the circulation in a finger or toe appears to intensify the action of the drug enormously, as shown first by Corning, so that incisions may be made and even the bone gouged out without the slightest pain to the patient, as I have demonstrated within the last few days.

Finally, a modification of Reclus's method which consists in employing a drug of equal analgesic power with cocaine but of far less toxic energy and of bringing up the specific gravity of the solution to about that of the blood by the addition of chloride of sodium has come into use which bids fair to yield the most important results. The *rationale* of this modification I should like now to place before you. It is described in a very able paper by Dr. Braun of Leipsic, read before the Congress of German Surgeons last Easter at which I was present. It is also dealt with in another paper by his assistant, Dr. Heintze, since published.

In the first place, it is based upon the observation that in eucaine β (Benzoyl-trans-vinyl-di-aceton-alk amin) we have a drug which is equal to cocaine in analgesic properties while it is far less poisonous, standing in the last respect to cocaine as one to four or five In the next place, it is found that it can be used in extreme dilution, even up to one to 1000 or less, without forfeiting its analgesic effects. Thirdly, it has been proved that the addition of eight per 1000 of chloride of sodium to the solution improves its analgesic properties largely and has other desirable effects besides. Such a solution, consisting of eucaine one part, chloride of sodium eight parts, and water 1000 parts by weight, is the one which I am employing before you to day. It can be used practically in any amount without danger of poisonous effects, seeing that at least 10 oz. would have to be injected before the supposed maximum dose of eucaine β had been reached. As a matter of fact, 300 c.c., or 10¼ oz, have been injected in at least one operation without any ill-effects. But this will rarely be necessary.[1]

In considering the action of this fluid please keep prominently before you the fact established by Corning in America and Feinberg in Russia that cocaine applied closely to a sensory nerve-trunk produces analgesia over its whole distribution. Let me reproduce Dr. Braun's diagram to illustrate this (Fig. 1). It is quite plain that a proper fluid injected at a point where two sensory nerve filaments cross (II) may produce analgesia in both, and that if the injected fluid become diffused over a larger area (I) it may ultimately reach neighbouring filaments belonging to other nerves in one or other direction. As seen in the diagram it might meet with a nerve on the right (N 2) and affect it while missing that on the left (N 1). The same amount of fluid, however, as that employed in puncture II if injected near the trunk of the nerve at IV would produce nearly the same effect as that due to the diffusion marked by I, missing only the twig of N 1 which does not cross with the other of N 2. But if the same small quantity were injected into both the nerve trunks at III and IV the maximum of analgesia area would be reached without much diffusion of the fluid. It is this latter effect which is aimed at in the infiltration process, where by many injections of a very dilute solution over the course of sentient nerves it is hoped that the area of influence of each will overlap and so that no escape of any nerve twig shall be possible.

But of course the analgesia so produced might possibly result from various factors in the injection. It might be due (1) to the temperature of the injected fluid, (2) to the mechanical pressure exerted by the injected fluid upon the terminal sensory filaments, or (3) by the anæmia similarly produced; it might be due (4) to destructive chemical action on the nerves and tissues, or (5) it might be, finally, a specific but non-destructive effect of an injected drug upon the nerve.

Now, Dr. Braun and Dr. Heintze set themselves to ascertain by experiment how far these various factors played a part in local infiltration analgesia. The observations were made upon their own arms in the morning hours. This latter point was important because it was found that later in the day the sensibility of the skin is reduced, probably as the effect of taking food. It was also noticed that after alcoholic drinks it was easier to produce analgesia. Both of these points we must carefully bear in mind when employing this method.

The most important property of watery solutions in relation to the questions involved was their osmotic powers. They either gave or took water from the tissues or, at a certain concentration, they were indifferent solutions to which the tissues did not react at all. It is now known that all watery solutions *which have the same freezing-point* are isosmotic—i e., they either equally give or take water from the tissues or are indifferent in this respect to the latter. It has also been observed that plain distilled water injected into the skin rapidly produces two effects. In the first place, there is pain more or less severe for the moment and then transient anæsthesia. The first of these appears to be due to osmotic tension and the second likewise. These effects of osmotic tension on the sensory nerves which may be called simply injection irritation and initial paralysis are easily observed by injecting pure water at first into the skin and then water with graduated amounts of a chemically indifferent salt such as chloride of sodium. It was found that all such solutions which have nearly *the same freezing-point* as the normal fluids of the body are indifferent to the tissues—that is, they produce no osmotic changes.

Other observers have placed the freezing-point of blood, lymph, and exudation at – 0 55° C. as nearly as possible. A watery solution of chloride of sodium of 0 9 per cent. has the same freezing point and is consequently osmotically indifferent to the tissues. All stronger concentrations withdraw water from these and cause pain; all weaker solutions cause the tissues to swell, also causing pain, and all the more the nearer they approach to pure water. It is unnecessary to go into this at any great length, but you will better understand the bearing of the whole question upon the effects of injection upon sensory nerves if you look at this diagram (Fig. 2) from Dr. Braun to illustrate the osmotic effects upon the latter of watery solutions at various concentrations *down to the freezing-point of blood* and below it. Here we have on the horizontal line A B the stages of graduated concentration of a solution of common salt from 0 per cent., or pure water, to 10 per cent. The freezing-point below 0° C. of a part of these solutions is also given in the lowest lines of figures. The dark continuous curved line represents the sensory irritation indicated by pain which arises when the fluid is first introduced as pure water and then on the addition of increasing amounts of chloride of sodium. The broken line represents the transient sensory paralysis due to osmotic tension under similar conditions. The height of the curve corresponds, of course not mathematically but accurately enough, to the intensity of the irritation and the paralysis. In the middle stands the osmotically indifferent 0 9 per cent. solution of chloride of sodium. When *warm* it produces neither irritation nor paralysis of sensibility and is rapidly absorbed without leaving even a trace of change in the tissues. When injected into his own arm Dr. Braun found an apparently indifferent zone reaching from the 0·55 per cent. solution to about 2·0 per cent. in which neither injection-pain nor appreciable change of sensibility took place. But the same solution of 0·9 per cent. injected into inflamed tissues only gave a zone of insensibility in the immediate neighbourhood of the point of injection. You see also that starting backwards from a solution of 0·9 per cent. of common salt pain begins at about 0·5 per cent. and ascends until it reaches its maximum intensity with pure water, 0·0 per cent., while the immediate paralysing effect of osmotic swelling runs *nearly* parallel. An osmotic paralysis without irritation does not take place at all. Pure water besides produces in some cases distinct osmotic necrosis with exudations of inflammatory matter, and again even at the other end of concentration with 0·2 per cent. of salt this is seen. Stronger solutions than 0·9 per cent. show the effects of the removal of water from the tissues (B) up to 10·0 per cent. These consist also in irritation and sensory paralysis as seen in the right-hand curve.

---

[1] The same amount has been injected into a rabbit without any evil consequences.

FIG. 2.

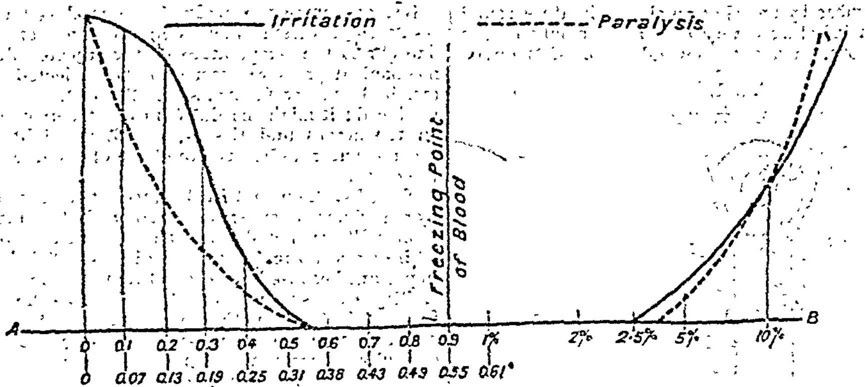

Diagram to illustrate the osmotic effects upon nerves of watery solutions of NaCl at various concentrations. The lower line of figures are – degrees C. The line marked 0 to 10% represents ascending concentrations of NaCl per cent.—e.g., 0·9% = 9 pro mille.

The proof that the changes just described are due to osmotic processes lies in the fact that we may inject large quantities of 0·9 per cent. of chloride of sodium into the tissues *until* extensive mechanical œdema is produced without lowering the sensibility, provided the fluid is at the body temperature. Cooling of the same solution to 0·0° C. or lower produces very transient anæsthesia in addition to the irritation. Water, on the other hand, warmed *to 50° or 55° C.* leaves behind painful infiltrations without lowering the sensibility. The proof that the analgesia is not produced by pressure anæmia lies in the fact that an area may be distended to any amount with 0 9 per cent. of salt solution if it is kept at body temperature without disturbing the sensibility in the slightest degree. Also if a finger be tied with an elastic band and become engorged only paræsthesia results, not analgesia. A further proof that the effects described are due alone to osmotic changes is found in the fact that a number of other chemically indifferent substances produce the same effects if used in the same way. Dr. Braun gives a long list of these salts which I should like to show you did time permit, and finds that in the indifferent *zone* which these salts produce in certain watery concentrations their freezing-points are practically the same. Take, for instance, a solution of cane sugar. This at a concentration of from 5 to 8 per cent. has the same osmotic tension as 0·55 per cent. of chloride of sodium and injected into the skin produces like the latter no change of sensibility. But with a solution of only 3 per cent. sugar, which corresponds about to a 0·3 per cent. solution of common salt, a moderate injection pain and lowering of sensibility are produced. But the addition of 0·6 per cent. of salt to the sugar solution neutralises its osmotic effect again and the mixture produces neither pain nor anæsthesia. So much for the physical effects of salt and other solutions on the nerves and tissues, though I should like to touch upon other illustrations of the point from the paper quoted if I had more time.

Let us now consider the chemical action of solutions of various kinds on the sensory nerves. Of course we are concerned with those which are indifferent. There are many which are powerfully destructive and which cannot be injected even in great dilution. But of the indifferent it is shown that at the same concentration which yields a freezing-point the same as a 0·9 per cent. solution of common salt there is the same zone free of irritation and analgesia and no tissue change. I should like to give you the reasoning on this point in detail but it would carry us too far. It is well worked out by Dr. Braun in regard to many bodies. He also shows incidentally that even hydrochlorate of morphia exercises no *local* lasting analgesic effect except so far as it very slightly adds to the specific gravity of the water in which it is dissolved and that in plain watery solutions of from 4 per cent. to 1 per cent. it produces ever-increasing injection-pain and transient anæsthesia which are only diminished by the addition of 0·6 per cent. of chloride of sodium, so that its addition as in Schleich's solution is useless.

There remains now only the specific action of the analgesic solution to be considered. The effect of cocaine in this respect would be interesting to work out, but for the following reasons, as well *as to save* time, I pass it by. We have, namely, in eucaine β a substance equal to it in analgesic properties and superior to it in possessing only a fourth or fifth of its toxic dangers. Cocaine besides is destroyed by boiling; eucaine β is not, and can *therefore be sterilised*. The freezing-point of its various solutions is almost identical with those of cocaine of the same strength. It keeps well and is cheap. For all these reasons it appears the best substance for our purpose, at all events for the present. But it is plain from what has gone before that in preparing any solution of eucaine β or cocaine we must employ warm osmotically *and* chemically indifferent fluid with a freezing-point of about – 0·55° C. as a medium so as to exclude all the physical effects of the injection *per se* and to leave the pure specific action of the paralysing drug to operate alone. With common salt solution in water of the strength *of 0·8 per cent.* and at the body temperature we have such a fluid equalling in its freezing-point that of the blood—namely, nearly – 0·55° C. To this we have only to add 0·1 per cent. of eucaine β and a fluid is furnished which meets our wants, its *freezing-point* being equal *to nearly 0·9 per cent. of* salt or – 0·55° C. We might make the eucaine β even weaker than this—1 in 1000—without forfeiting its specific action, but we should gain little by this and its action would be slower.

And now how do we make and use this fluid in practice? Perhaps the best course to pursue is to have powders made ready containing enough eucaine β and pure crystalline chloride of sodium for a couple of ordinary operations. I have had a number of such powders made up by our dispenser, Mr. Wilson, containing three grains of eucaine β and a certain quantity of chloride of sodium. One of these is boiled for a few minutes in seven ounces of distilled water and gives us a sterile solution of eucaine β one part, chloride of sodium eight parts, and water 1000 parts by weight. To use this it is well to have a special syringe such as this designed for the purpose (pattern shown). It holds 10 c.c. and has an asbestos piston in a glass cylinder which fits perfectly without any leakage. It can all be taken to pieces and boiled. It can be used, as you have just seen, either with a screw action on the piston-rod or by pull and push which is convenient for filling or emptying rapidly. To it are fitted with bayonet action either fine needles for the skin or coarser for the deeper parts One of each is bent at an elbow for use in cavities This syringe is filled with the above solution at a little above the body temperature and is armed with the finest needle. The latter is now thrust obliquely under the epidermis until its eye is buried. A few drops of the solution are then forced out by the screw when a white plaque is formed Through this which is quite anæsthetic the needle is forced deeper in various directions while the fluid is pumped out, causing a thorough infiltration of the areolar tissues and if necessary of the muscles and periosteum all over the area to be operated on until an artificial mechanical œdema is produced and presumably all the nerves of the part are steeped in the fluid. The coarser needles are more suitable for the deeper structures. Finally, the smallest needle is thrust horizontally under the epidermis all along the course of the proposed incision (the screw being turned meanwhile) until a long plaque is produced of white colour and raised. In about five to 10 minutes the part will be in a state of analgesia. The operation will then be begun and if a deep one more fluid will be forced into the deeper tissues in its course.

And now as to the preparation of the patients. In the first place, they should *not* be operated on when fasting. All are agreed upon this point. They should have had a nutritious meal shortly before. This has its advantages and its drawbacks. It is beneficial to most patients to face a long operation such as an abdominal section or radical cure of hernia with a feeling of satisfied hunger and at their fullest strength. As vomiting is not to be anticipated there is no reason for not giving food. Moreover, the sensibility of the skin seems to be blunted after the use of alcohol, so that it is well to give an egg beaten up with five ounces of milk and one ounce of brandy half an hour before operation. Among the drawbacks to feeding before operation is the chance that it may be necessary to produce general anæsthesia before the operation is over for one reason or another, in which case food in the stomach is undesirable. Again, if there were stercoraceous vomiting in a hernia case or in one of internal obstruction food would be undesirable unless we had previously washed out the stomach which, by the way, should always be done in such cases It is also a question whether we ought to allow food to pass through bowel which has been strangulated until after the lapse of a day or two. But we might give brandy in such a case without fear.

As to the drawbacks of local infiltration analgesia a good deal can be said. In the first place, the patient is conscious and this alone may prove a very great difficulty. It is probable therefore that for nervous people, and for children especially, the method will have but a very limited application among us here Again, there is no motor paralysis and if in a deep dissection pain is felt the patient may move and embarrass the surgeon But with experience in the use of the method we see but little of this and very large operations are done without trouble from this drawback. My list of operations performed under this form of analgesia during January includes—radical cures of hernia, three; abdominal section for acute general peritonitis, one; wiring patella, one; removing wire, one, osteotomy, one; varicocele, one; empyema, one; and ischio-rectal abscess, one Another objection to infiltration is that it produces an extensive artificial œdema which masks anatomical details considerably. But a little experience gets over this, especially as after the incision the excess of fluid soon leaks away. Finally, the use of the drug during an operation may cause a little delay, but not much.

It remains to be seen whether the advantages of this local analgesia outweigh in the long run the drawbacks some of which I have alluded to in the case of large operations. For the smaller operations it certainly has a large field and in many of the larger procedures it has seemed to rival general anæsthesia with its well-known dangers. But whatever may be the ultimate verdict on this method—and I am not here as its advocate but rather to study its merits and demerits with you—it appears to be a procedure which deserves very careful attention, and it certainly is most astounding as well as intrinsically interesting to see an operation such as a radical cure of a large hernia done while the patient talks and (as you saw a few days ago) laughs as he enjoys a cup of tea while you are dividing or stitching up the abdominal walls and as he describes to you his sensations. For again remember, in conclusion, that the method does not produce total anæsthesia or motor paralysis but only analgesia.

I shall now operate on the patient for the radical cure of hernia on whom I have just demonstrated the infiltration method and on another for trouble in the knee and you will see for yourselves the result.

A CASE OF

BILATERAL PARALYSIS OF THE LARYNGEAL ABDUCTORS SUCCESSFULLY TREATED BY THE REMOVAL OF THE ISTHMUS OF A BRONCHOCELE.

BY SAMUEL LODGE, JUN., M.D. DURH.,

SURGEON TO THE EYE, EAR, THROAT AND NOSE DEPARTMENT OF THE ROYAL HALIFAX INFIRMARY.

A SCHOOLBOY, aged 14 years, was brought to me by Dr. Bell Graham of Bradford on July 10th, 1897, complaining of difficulty in breathing. Hereditary tendencies and family health presented no features of importance. He had had good health previously. There was no history of injury, metallic poisoning, or residence in an endemically goitrous district. For the last seven years, after exertion, his breathing had been noisy when awake and especially so during sleep. These symptoms had gradually increased until now he was precluded from outdoor games of any kind with his schoolfellows and his loud breathing made visits to the seaside or country impracticable owing to the disturbance of the sleep of others in the same house. The boy's relatives only obtained sleep at home by insisting on his keeping very still all day, otherwise his breathing was heard all over the house. The patient was intelligent and well developed. Whilst sitting still his breathing was easily heard and obviously quickened. His voice was almost normal in sound but it was noticeable that talking any length of time increased his respiratory embarrassment. After having been made to run a short distance he became slightly cyanosed, his mouth was held open, his supraclavicular and epigastric regions together with the lower intercostal spaces were markedly indrawn and there was a very loud inspiratory and expiratory stridor. There were no signs of present or past disease of the chest. Laryngoscopically during quiet respiration the glottic chink was considerably narrower than normal. On forced inspiration the vocal cords were approximated. On phonation the vocal cords adducted perfectly, although the patient's voice sounded rather harshly as if voice-production were faulty. The larynx was otherwise normal. A diagnosis of abductor paralysis of the vocal cords was accordingly made. By a process of exclusion we concluded that the cause was in the neck On examining the neck both lobes and the isthmus of the thyroid gland were enlarged. The lobes of the thyroid dipped slightly beneath the clavicles. The isthmus could be readily mapped out by the fingers and thumb as a broad thick strap across the trachea. On palpation the thyroid, although much firmer in consistence than the soft goitre of adolescents, lacked the stony hardness of malignancy. The goitre had never attracted much attention, but careful inquiry elicited the information that it had grown gradually, though slowly, during the last seven years. No protrusion of the eyeballs or other marked symptoms of exophthalmic goitre were present. Although the goitre had not been treated previously the patient had been carefully treated medically, surgically and expectantly since [illegible] his symptoms. We decided to relieve pressure on the recurrent laryngeal nerves by reducing the size of the goitre. The seductive portrait of the patient under the care of Mr. Pitts in Treves's "System of Surgery" was in my mind when I prescribed iodide of potassium for this purpose. This drug was exhibited cautiously but thoroughly for five or six weeks, beginning with five grains thrice daily and ending with 60 grains thrice daily. The iodism increased the respiratory difficulties very much. During this time we tried to increase the rate of progress by also prescribing thyroid extract. The favourable abstracts of reports of this method of treatment in the *Journal of Laryngology* for 1896 by Marie and other continental writers suggested this treatment. The patient was kept in bed, accurate observations were made regularly, but the typical toxic symptoms compelled us to stop the thyroid after we had given from 15 to 30 grains daily for three weeks. Neither remedy appeared to reduce the size of the goitre. By September, 1897, we had convinced ourselves that if any relief were to be obtained within a reasonable time it must be by surgical means.

On Sept. 5th, 1897, assisted by Dr. Bell Graham and Dr. J. Guy, I made a median incision over the centre of the easily-mapped-out thyroid isthmus about three inches in length. The isthmus was cautiously separated from the underlying structures and the attachments of the isthmus to the thyroid were transfixed by an aneurysm needle armed with a double ligature. The ligatures were tied and the isthmus was removed. The excised portion was about one inch in length vertically and wider than was anticipated owing to its having been compressed laterally when *in situ* by the lateral lobes. The trachea was not "scabbard like" and there was no immediate improvement in the breathing which at the time was very bad owing to the patient taking the anæsthetic badly. The progress of the case was uneventful. A month afterwards the boy expressed himself as feeling "a little easier" but exertion readily brought on stridor. On March 11th, 1893, the father reported that "they could not see any improvement." About the beginning of April his parents stated that "the boy was able to run as well as any other boys and that they were no longer disturbed in their sleep by his breathing." When the patient was shown to the Leeds and West Riding Medico-Chirurgical Society at the November meeting no abnormality of the larynx could be detected laryngoscopically. The goitre had disappeared and his neck measurement, which before the operation was 14 inches, was 13 inches, in spite of his being a year older and of his having grown considerably since the operation.

The only case recorded in British medical literature which I have been able to discover on almost all fours with this one is related shortly in the late Sir Morell Mackenzie's classical work.[1] The patient, "aged fifteen years—a tall lad—when perfectly quiet could breathe fairly well, but on the slightest exertion he experienced great dyspnœa and during sleep made a loud noise in his breathing. On examining the neck a moderate sized but very hard bilateral goitre was perceived and on using the laryngoscope the abductors of the vocal cords were found to be paralysed on both sides. The adductors did not seem to be at all affected and the voice was perfectly normal. By varied treatment extending over several months the bronchocele was cured and the action of the vocal cords became natural." In this case the isthmus of the thyroid does not appear to have been large. Sir Duncan Gibb was first led to suggest the feasibility of removal of the isthmus by observing "several cases of enlargement of the thyroid gland affecting one or both of the lateral lobes and implicating the isthmus."[2] In 1870 a post-mortem examination on a young man enabled him to prove that in some cases, "if not relieved by treatment the lateral lobes, which in their enlargement sometimes spring from the isthmus itself, may extend on either side of the trachea itself and completely encircle it. The consequence of this is that the tube is compressed laterally and its form becomes oval, with a very narrow passage to breathe through, which sooner or later ends fatally." In 1874 Mr. Holthouse operated on two females for Sir Duncan Gibb with the happiest results. In each case the trachea was greatly compressed and relief was speedily manifested. In 1883 Mr. Sydney Jones reported in THE LANCET a case of "enlargement of thyroid gland in a male producing pressure on the trachea and serious attacks of dyspnœa; removal of isthmus; atrophy of lateral lobes; cure."[3] In this case the patient was a labourer, aged 18 years. The duration of symptoms was for seven or eight years. The patient was quite well in less than two months. Mr. Sydney Jones's brilliant series of cases have shown us that in the words of Sir William Mac Cormac it is "a method of treatment which is comparatively simple, easy of execution, and promises excellent results in suitable cases"[4] and, further, that where the same symptoms are produced by an innocent enlargement of the thyroid without an hypertrophied isthmus removal of portions of the lateral lobes encroaching mesially on the trachea may be done quite as safely and with the same beneficial results as in those cases where the isthmus alone is excised.

In all the cases referred to I have been unable to find any reference to laryngoscopical examination. The pressure, judging from the speedily successful results, must have respected the recurrent laryngeals and the "scabbard-like" condition of the trachea readily accounted for the whole of the dyspnœa, whereas in this case six months had elapsed before the patient was obviously much better. Nor could we reasonably have expected more speedy results seeing that laryngoscopically the dyspnœa could be readily explained by pressure on the recurrent laryngeals producing the abductor palsy. Finally, I wish to express my indebtedness to Mr. Jacobson's "Operations of Surgery,"[5] not only for the valuable *résumé* which it contains of this operation but also for the ease with which I was thus enabled to look up the literature on the subject.

Bradford.

THE DISTRIBUTION AND ORIGIN OF TUBERCULOSIS IN CHILDREN:

AN ANALYSIS OF POST-MORTEM RECORDS IN 77 CASES WITH REMARKS THEREON.

BY LEONARD G. GUTHRIE, M.A., M.D. OXON., M.R.C.P. LOND.,

PHYSICIAN AND PATHOLOGIST TO THE CHILDREN'S HOSPITAL, PADDINGTON-GREEN; ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE NORTH-WEST LONDON HOSPITAL.

IN an interesting letter to THE LANCET of Dec. 17th, 1898, Dr. Walter Carr drew attention to the statement recently made by Sir Richard Thorne[1] that deaths from tabes mesenterica in children under one year and also tuberculous meningitis have decidedly increased during the years 1891-95. The increase in the number of deaths from these causes Sir Richard Thorne attributed to the reception of tuberculous infection into the alimentary tract. It has been shown by experiment that guinea-pigs when fed on tuberculous material soon develop tabes mesenterica; also that cows with tuberculous udders give tuberculous milk. The inference from these facts is that infants who are presumably fed chiefly on milk become tuberculous by drinking it. Dr. Carr from his records of post-mortem examinations at the Victoria Hospital for Children proves that tabes mesenterica is rare in children under two years of age, almost unknown in those under one year of age, and he invites expressions of opinion from other hospitals for children on this point. His own opinion is that the infection of tuberculosis in children is derived more frequently from the respiratory than from the alimentary tract, and that tuberculous meningitis is more often due to infective centres in the chest than in the abdomen. He regards the alleged increase of tuberculous meningitis as owing to increased correctness in diagnosis, whilst increasing incorrectness in diagnosis explains the alleged increase in tabes mesenterica amongst infants.

In order to arrive at conclusions on these points I have tabulated my own notes on 77 post-mortem examinations made on children dying from tuberculosis in the Children's Hospital, Paddington-green, during a period of eight years ending in December, 1898. The number of cases is small and does not convey any idea of the great mortality from tuberculosis amongst children treated at this institution. Parents in many cases have refused their consent to the holding of post-mortem examinations, and so have hindered the accumulation of facts which might have aided in this inquiry. Many children have been discharged as incurable during these years and are known to have subsequently died from phthisis.

Total		57	Total		42

Both sets of glands were found caseous 15 times. In 3 cases neither set was implicated. In 12 cases the condition of the glands is not mentioned. More than one set of organs was sometimes found affected in the same patient.

Thus, tuberculosis of the various thoracic organs was found 105 times, of the various abdominal structures 102 times, of the brain and meninges 41 times, and of the bones and joints six times Although the numbers of times that tuberculosis of the thoracic and abdominal organs was found are numerically almost equal in this series, the figures do not adequately represent the proportion of thoracic to abdominal phthisis, for the number of organs and structures in the abdomen is greater than in the thorax. In the thorax only three structures, lungs, pleura, and lymphatic glands, need be considered; the solitary case in which the heart and pericardium were affected may be set aside. In the abdomen the structures in which tuberculosis was found are seven—namely, peritoneum, intestines, lymphatic glands, liver, spleen, kidney, and pancreas. For purposes of comparison we may deduct from the abdominal cases those of splenic and hepatic tuberculosis, 31 in all, as being unimportant and also those of renal and pancreatic tuberculosis (eight cases), leaving only those in which the peritoneum, abdominal glands, and intestines were involved. We have then only to compare the frequency of pulmonary phthisis with that of tabes mesenterica and the figures appear as follows: thoracic tuberculosis was found 104 times and abdominal tuberculosis was found 63 times. Adding to these figures the number of times that the thoracic and abdominal glands were found to be caseous (thoracic 46 times and abdominal 31 times) we find the totals are: thoracic tuberculosis 150 times and abdominal tuberculosis 94 times. Numerically, therefore, thoracic tuberculous affections are in excess of abdominal to the extent of at least one-third.

The starting-points of tuberculosis in children.—The method of decision is difficult and perhaps not devoid of fallacy. One can only attempt to ascertain in which organ or organs the tuberculous process is most advanced and assume that these have been primarily affected. When many organs in different parts seem equally involved it is practically impossible to come to a conclusion. On the other hand, it may not follow of necessity that the structure found most affected was the first to suffer. Tuberculosis may be set up in one place but remain quiescent there, so far as its local manifestations are concerned, yet bacilli may be disseminated thence to other and distant parts and cause rapid and extensive destruction in them. Hence conclusions as to the primary seat of mischief based on the degree of local damage found may be erroneous. However, this is the principle upon which other investigations on the subject have been made and on the whole it has led to results similar to my own.

The figures in Table II. show that in 77 cases thoracic tuberculosis was most prominent and apparently primary in 42 (54·5 per cent.), and abdominal phthisis in 19 (24 6 per cent.). Of the remainder (16) the thoracic organs were as much affected as the abdominal in seven. In one either the bronchial glands or hip had been first involved. In one the origin was either in the kidneys or hip, in one it was articular, and in six it was unknown.

Glandular origin of tuberculosis.—The thoracic glands were found in a state of caseation 46 times and the abdominal glands 31 times. Both sets were caseous in

15 cases, which must therefore be deducted from the total, in three neither set was affected and in 12 their condition was not noted. Thus the glands were caseous in 62 cases (80·5 per cent.). But I have not regarded mere caseation as evidence of primary glandular infection and I can only trace the origin of tuberculosis with any degree of certainty to the glands in 32 cases. It was apparently in the thoracic glands in 17 cases and in the mesenteric glands in 15. This reduces the total percentage of primary glandular affection to 41·5 per cent. This percentage is considerably below that given by other observers. Thus Dr. Walter Carr[2] found a glandular origin in 72·5 per cent. of his cases; Dr. Sims Woodhead[3] traced the origin of tuberculosis to caseous bronchial glands in 75·6 per cent., to mesenteric glands in 78·7 per cent., and to mesenteric glands alone in 14 out of 127 cases. MM. Rilliet and Barthez[4] found the origin in caseous bronchial glands in 79 per cent. and in mesenteric glands in 46 per cent. of cases. Simmonds[5] discovered caseous bronchial and tracheal glands in 73 per cent. and caseous mesenteric glands in 46 per cent., whilst Dr. Walter Colman[6] attributed the origin to caseous thoracic glands in 79 per cent. and to mesenteric glands in 66 per cent. of his cases. The discrepancy between these statistics and my own may be due to the fact that I have discarded the glands as the primary source of infection unless they have been both obviously caseous, and also associated with miliary, or at all events comparatively recent, tuberculosis elsewhere. In my own cases of tuberculous meningitis to which I shall presently refer the percentage of primary glandular infection was probably 70·7 per cent., which more nearly approaches the results given by other observers. In cases of tuberculous meningitis it is usually easier to come to a decision as to the primary source than in cases of death from pulmonary or abdominal phthisis because meningitis soon kills, whereas pulmonary or abdominal phthisis must be far advanced before becoming fatal and in the latter cases it is very difficult to decide whether the glands, lungs, or intestines show the most advanced tuberculosis.

Comparative importance of pulmonary and abdominal phthisis in children.—We have seen that in 77 cases the proportions of thoracic to abdominal tuberculosis were as three is to two, also that thoracic tuberculosis was apparently primary in 54·5 per cent., whilst abdominal phthisis was apparently primary in 24·6 per cent. of cases. The difference is yet more striking when the causes of death are considered. Only four of the whole series actually died from tabes mesenterica. Three of these were over six years of age, one was aged between one and two years, but in this case fatal generalised peritonitis was caused by rupture of a mesenteric glandular abscess and there were no intestinal ulcers. The cause of death in 30 of the cases was pulmonary phthisis. 41 died from tuberculous meningitis, one from diphtheria, and one from purulent pericarditis:—

Table III. shows that tabes mesenterica is not directly fatal in young children. In the great majority of cases it only existed as part of generalised tuberculosis, giving rise to no characteristic symptoms, and it was unrecognised during life except when the mesenteric glands were sufficiently large to be palpable through the abdominal wall. Hence I share the doubts expressed by Dr. Walter Carr as to the truth of the statement recently made that there has been a large increase in the mortality from tabes mesenterica amongst children under one year of age during the years 1891–95. Such statements, when based on the Registrar-General's reports, unless supported by records of post-mortem examinations, are not reliable. The increase in the returns of death certificates under this heading is doubtless due, as Dr. Carr holds, to the prevalent superstition that every wasting infant who has also diarrhœa is suffering from "consumption of the bowels." Medical men are forced to aid and abet this superstition, for by fostering it they do not fall into discredit when their patients die, whilst if their patients recover, the medical attendant's reputation becomes greatly enhanced. The table, however, shows that in children aged between one and two years tabes mesenterica was more frequent than at any other age. Yet six of the eight cases died from pulmonary phthisis and two from tuberculous meningitis. Tabes mesenterica may therefore be set up at a very early period of life (one of my cases was only three months old), although it is never the direct cause of death in infants.

TABLE III.—*Showing the incidence of intestinal ulceration, the ages at which it was found, and the cause of death in 27 cases.*

Ages.	Ulceration.		Mesenteric glands.		Not mentioned.	Cause of death.	Total.
	Advanced.	Slight.	Enlarged.	Caseating.			
Under 1 year ...	—	3	—	2	1	Tuberculous meningitis ... ... 2 Pulmonary phthisis 1	3
From 1 to 2 years	5	3	1	7	—	Tuberculous meningitis ... ... 2 Pulmonary phthisis 6	8
" 2 to 3 "	2	1	—	2	1	Tuberculous meningitis ... ... 1 Pulmonary phthisis 1 Diphtheria 1	3
" 3 to 4 "	2	—	1	1	—	Tuberculous meningitis ... ... 1 Pulmonary phthisis 1	2
" 5 to 6 "	1	2	1	1	1	Tuberculous meningitis ... ... 1 Pulmonary phthisis 2	
" 6 to 7 "	2	—	—	2	—	Pulmonary phthisis 2	2
" 7 to 8 "	1	—	—	1	—	Tuberculous meningitis 1	1
" 8 to 9 "	4	—	1	2	1	Pulmonary phthisis 1 Tuberculous peritonitis 3	4
13 years	1	—	—	1	—	Tuberculous meningitis 1	1
Totals	18	9	4	19	4	—	27

The causes of death in these 27 cases were as follows: tuberculous meningitis, 9; pulmonary phthisis, 14; tuberculous peritonitis, 3; and diphtheria, 1.

TABLE IV.—*Showing the Probable Origin of Tuberculous Meningitis in 41 Cases.*

Thoracic	Lungs	5	Unknown	General miliary tuberculosis ...	1
	Lungs or mediastinal glands ...	5		No tubercle elsewhere	1
	Mediastinal glands	14		Head only examined	3
Abdominal	Ulceration	1	Doubtful	Thoracic or mesenteric glands ...	2
	Mesenteric glands or ulceration ...	2	Articular ...	Elbow or knee ...	1
	Mesenteric glands	6			

Of these 41 cases the origin was: thoracic in 24 cases (58·5 per cent.) abdominal in 9 cases (21·9 per cent.); and glandular either in abdomen or thorax (probably) in 29 cases (70·7 per cent).

The ages of the 41 patients in the above table were as follows:—

Under 1 year	5 cases.	From 5 to 6 years... ...	5 cases.
From 1 to 2 years ...	11 "	" 6 to 7 "	1 "
" 2 to 3 "	5 "	" 7 to 8 "	3 "
" 3 to 4 "	3 "	" 8 to 9 "	4 "
" 4 to 5 "	2 "	" 9 to 14 "	2 "

In 24 cases, therefore, of 41 (58·5 per cent.) the origin of meningitis was in all probability thoracic. In nine only (21·9 per cent.) it seemed to have been abdominal. In two of the thoracic cases otitis media might have been the immediate cause of the meningitis. In one there was disease of the tarsus, but the affection of the lungs was also far advanced. In two there was strumous dactylitis, but in one of these the bronchial glands and in the other the bronchial and mesenteric glands were caseous. In one the hip-joint had been excised some months before death, but the wound had quite healed, whilst the bronchial glands were caseous.

[5] Beitrag zur Statistik in Anatomischer Tuberculose im Kindesalter, Dissertation, Kiel, 1879.

[6] Brit. Med. Jour., vol. ii., 1893, p. 740.

One had had a tuberculous testis removed shortly before death but the cause of the meningitis was probably a large mediastinal abscess In one the origin was definitely articular (elbow and knee), no tuberculous foci being found elsewhere in the body In the two doubtful cases the origin might have been either in the thoracic or the abdominal glands Of the five cases of unknown origin, one had general miliary tuberculosis in one no tubercle was found elsewhere in the body, but the internal ear does not seem to have been examined In the remaining three only the head was examined The table illustrates the well known fact that tuberculous meningitis is almost invariably secondary to tuberculous affection elsewhere, also that its origin is far more commonly thoracic than abdominal, and, finally, that the commonest source of meningitis is from caseating glands, chiefly in the thorax

Alleged increase in tuberculous meningitis —It has been stated in the Harben Lectures for 1898 that deaths from tuberculous meningitis as well as from tabes mesenterica are increasing in frequency So far as the year 1898 is concerned I believe that there has been an increase in the number of deaths from meningitis in children, but I have attributed the increase to the effects of the very severe epidemic of measles which swept the country in the autumn of 1897 and the first quarter of 1898 Pulmonary tuberculosis is a common sequela to the bronchial catarrh of measles, hence the increase in meningitis only means an increase in pulmonary phthisis in children Yet it must be remembered that tuberculous meningitis like tabes mesenterica, is often wrongly diagnosed In a bygone age pneumonia was called "brain fever", now, when a child has pneumonic delirium he is usually supposed by the public to be suffering from tuberculous meningitis

Mode of entry and spread of tuberculosis in children —The local inoculation of tubercle through the skin need not concern us here We have only to consider the entry of tubercle bacilli by the respiratory and by the alimentary tracts In the one case it is usually assumed that they are inhaled directly into the lungs, in the other that they are swallowed in food and so pass directly into the alimentary tract The arguments in favour of the inhalation theory are—(1) that pulmonary tuberculosis is far more common in children than mesenteric and that the alleged increase in the death rate from tabes mesenterica in infants under one year, has no foundation in fact, (2) that the proportion of caseating thoracic glands is much greater than that of caseating mesenteric glands and the degree of caseation in the former is usually more advanced than in the latter, and (3) that glands are usually affected directly through the structures with which they are associated Hence the inferences drawn are that mesenteric tuberculosis is secondary in point of time frequency, and importance to thoracic, and that tuberculosis in children is more frequently due to inhalation of bacilli into the lungs than to their introduction by means of food, especially milk, into the alimentary tract This is, I believe, the gist of Dr Carr's contention and Dr W Colman agrees, saying "Without doubting the infection of milk in some cases I am led to attach more importance to the condition of the thoracic lymphatic glands, as the process was more advanced in them as a rule than in the mesenteric glands and in several they were extremely caseous when the mesenteric glands showed little or no change "[7]

I do not think there can be any doubt that in children there is a great preponderance of thoracic over mesenteric tuberculosis and that deaths from tabes mesenterica in young children are practically unknown, yet these facts do not prove that infection is from direct inhalation of bacilli into the lungs, nor do they disprove that bacilli entered by the alimentary tract On the other hand, the entry of bacilli into the alimentary tract does not prove that they have been introduced in milk or other food They may have floated in air entering the mouth and have been subsequently swallowed in food or mucus The great excess of infection of thoracic glands over that of mesenteric glands may be explained on other grounds than on the supposition that it is due solely to entry of bacilli through the lungs It must be remembered that the thoracic glands are commanded on all sides, for the lymphatic streams all converge in the thorax. Dr Sims Woodhead has demonstrated the course of tuberculosis through the pharyngeal and tonsillar structures, through the glands in the neck, then those in the thorax, and finally to the lung itself, in pigs He has also traced tuberculosis from a caseous or old calcareous mesenteric gland, through the chain of retroperitoneal glands up through the diaphragm to the posterior mediastinal and bronchial glands and so on to the lung [8] To these modes of access to the mediastinal and bronchial glands may be added those through the œsophageal lymphatic plexus The œsophageal lymphatics join the posterior mediastinal glands and also, near the root of the lung, the pulmonary lymphatic vessels which pass through the bronchial glands and the tracheal and œsophageal glands before terminating in the thoracic ducts The œsophagus has not as far as I know, been considered in this relation Yet although I have never found a tuberculous ulcer in the œsophagus of a child, the tube after death is usually in a most unclean condition, lined with slimy mucus and particles of food It is not, therefore, improbable that bacilli accompanying mucus or food may be carried almost directly through the œsophageal lymphatics into the mediastinal and bronchial glands and so in time affect the lungs

Infection of the lungs through the blood —Although tubercle bacilli are rarely found in the blood there can be no doubt that they must often exist in it We cannot explain the origin of tuberculous meningitis (in the absence of local tuberculosis such as middle ear disease) except on the supposition that the bacilli are carried to the brain by the blood A wandering leucocyte with bacilli in its maw, although endowed with powers of movement, can hardly make its way up the lymphatics against stream to the meninges The lymphatics all eventually meet in the thoracic ducts, and their lymph passes almost directly to the lungs through the right heart Hence if lymph picks up bacilli on its way through caseating abdominal and thoracic glands it must carry them into the pulmonary circulation. So the lungs are exposed to blood infection as well as to infection by direct inhalation of bacilli into the alveoli, whilst, as previously stated the reason why the thoracic glands are more prone to tuberculous infection than the abdominal may be because they are the meeting place of so many lymphatic streams On the other hand the mesenteric glands can only be affected either directly from the intestines or by bacilli brought to them in the circulation

Auto-infection —It has been suggested, and Dr Carr supports the view, that intestinal tuberculosis in young children may be due to deglutition of their own tuberculous sputa It is true that young children do not expectorate Yet as tubercle bacilli are not found in the sputa in cases of miliary tuberculosis one would expect secondary intestinal tuberculosis to be most marked in cases of advanced cavitation, when, presumably the sputa swallowed must be swarming with bacilli Yet I have not been able to satisfy myself that this is so Indeed whilst writing this paper I have made a post mortem examination on a child, aged between six and seven years, who died with more extensive cavitation than I have ever seen in one so young Both apices were converted into hollow shells During the three months she was under observation I am certain that she never expectorated at all and therefore must have swallowed an enormous quantity of infective material Nevertheless there was not the slightest trace of intestinal ulceration and the mesenteric glands were perfectly normal. A few nodules in the spleen were the only signs of abdominal tuberculosis The bronchial and posterior mediastinal glands were all enlarged and advanced in caseation Such cases seem to show that it must be exceedingly difficult to produce intestinal tuberculosis by swallowing tuberculous matter

To those engaged at children's hospitals who have for many years diligently propagated the doctrine that milk is the food for babes, the idea that they may have thereby aided in the propagation of tuberculosis is not a pleasant reflection Yet by a saving grace we have been accustomed to order the milk to be boiled, or at least scalded and this may perhaps allay our apprehensions Moreover, we have seen countless numbers of marasmic infants at once begin to thrive when fed on milk These are the very children who are supposed to be afflicted with consumption of the bowels, whereas they have merely suffered from the results of improper feeding It would be hard, indeed to think that we have saved them from one fate only to condemn them to another

The strongest argument after all, against milk as an important producer of tuberculosis is that children of the class to which hospital patients belong seldom get milk fresh from the cow. They are fed almost invariably on condensed milk and on cheap patent foods. Whatever may be said against these articles of diet they cannot be blamed for being tainted with bacilli—at all events, at the time they leave the manufacturers. Yet the number of deaths from tuberculosis among such children far exceeds that of deaths from other diseases. My experience among children of richer classes is limited, but leads me to believe that fresh cow's milk is rarely given to them. If they get milk at all it has been boiled until its chief virtues have left it together with any bacilli which it may have contained. It soon then disagrees and the infant is made to go through a course of proprietary foods which render it rickety and often scorbutic and in one way only lessen its chance of acquiring tuberculosis. The public are peculiarly tenacious of a particular fact once grasped and are apt to generalise too widely from it. The fact that some milk is tuberculous means to them that all milk is tuberculous, and the practitioner who ventures to prescribe it is regarded as an ignoramus or even worse.

---

[7] Brit Med. Jour , vol ii , 1893, p 740

[8] Channels of Inf

It would be futile to deny that a certain amount of danger and a considerable amount of difficulty attends the use of cow's milk as a diet for children. Still it will always remain the best of infant's foods. The public must be warned against regarding the aims and object of our sanitary authorities as a mere crusade against cows. Purify our dairies as we may, we shall still have bacilli amongst us. It is by making clean our habitations that we shall most effectually drive bacilli from our midst; and this is the ambition of the Association for the Prevention of Tuberculosis. The purification of our milk-supply is but a small part of its duties, and one might as well hope to eliminate tuberculosis by shutting up the monkey-house and aviaries at the Zoological Gardens as by banishing bacilli from our dairies alone.

Synopsis.—1. Thoracic tuberculosis in children is more common than abdominal in the proportion of three to two. 2. Tabes mesenterica as a cause of death in young children is practically unknown. 3. The preponderance of thoracic over abdominal tuberculosis is not necessarily and solely due to the direct entry of bacilli into the air passages. In addition to this mode of infection the lungs may be affected: (*a*) by bacilli entering the thoracic glands through the lymphatics of the pharynx, tonsils, and œsophagus above, and through the lymphatics of the intestines and the abdominal glands below; and (*b*) by the entry of bacilli through the thoracic ducts into the pulmonary circulation *viâ* the right heart. 4. Primary infection through the alimentary tract does not prove that food has been the sole source of evil. Therefore tuberculosis in children is not likely to be materially checked by purification of milk-supply alone. 5. The alleged increase of tuberculous meningitis of late years is probably due to pulmonary tuberculosis set up by severe epidemics of measles.

Upper Berkeley-street, W.

A WOMAN DISEMBOWELLED BY A COW RECOVERY.

BY THOMAS BELL, M.R.C.S. ENG., L.R.C.P. LOND.

ABOUT 7.30 A.M. on July 5th, 1898, a message arrived requesting my attendance at a village two miles away upon a woman who had just been tossed by a cow. No particulars of the injury could be obtained. Dr. A. W. Cook Young, my assistant, who attended as soon as possible, on seeing the greater part of the bowels external to a wound in the abdominal wall, decided not to attempt the reduction alone; he gave a subcutaneous injection of a quarter of a grain of morphia, applied flannels wrung out of hot water to the bowels, and returned for me. Having prepared everything which might be required I arrived at the house about 10 A.M.

The patient was a married woman, aged 42 years, and was the mother of 12 children. It appeared that she was crossing the cow-yard to feed some poultry when a cow tossed her into the air and she alighted on the left side of the head and left shoulder. On reaching the ground she managed to struggle to her feet and walked about 30 yards into the house where she at once fell on the floor. On examination I found a transverse wound six inches in length, the centre about the middle line, about one-third of the distance below the umbilicus towards the pubes. Some 18 inches of the transverse colon and the whole of the mesenteric portion of the jejunum and ileum were protruding through the wound—about 20 feet of the small bowels. I at once carefully washed the left side of the abdomen and wound with a one in 20 solution of carbolic acid and the bowels with a one in 40 solution and at the same time examined them for any injury and laid them on the left side of the abdomen. The left hand was partly introduced into the wound. The reduction was begun with the lower ileum, passing it through a small opening between the thumb and index finger downwards and at first towards the cæcum, afterwards directly downwards, the whole ileum and jejunum being replaced; the transverse colon and greater omentum were returned last to the abdomen. 12 chrome catgut sutures saturated in a one in 40 solution of carbolic acid were introduced deeply but not touching the peritoneum. On first seeing the patient I doubted whether she would survive the reduction, the shock having been so severe, but fortunately no hæmorrhage or injury to the bowel had occurred and when the reduction was complete and the wound had been sewn up she expressed herself as feeling better, "now her bowels were in their places again." *From the time of the goring to the end of* the reduction was about four hours. The wound was dressed with a one in 80 solution of carbolic acid and covered with antiseptic gauze and a towel was fastened over all. The temperature was 97·6° F. and the pulse was 120. She was ordered a milk and beef-tea diet and was given quarter-grain doses of morphia and ammonia. About 5 P.M. she was sick and as there was a complete absence of pain the morphia was discontinued, it being considered the cause of the sickness, and hydrocyanic acid, ammonia, and tincture of hyoscyamus were given.

The following brief notes tell the after-history of the case. On July 6th the patient was very comfortable. She was not in pain and there was no tenderness on pressure about the abdomen. The temperature was 98·7° and the pulse was 120. On the 7th there was no pain and she felt better, taking milk and beef-tea freely. The temperature was 99·7° and the pulse was 100. On the 8th she was sick at 2 A.M. without apparent cause. There was no pain. The temperature was 99·5° and the pulse was 94. On the 9th the wound was dressed. Union by first intention had taken place through the whole length of the wound which looked very healthy. There was no pain. The temperature was 98·4° and the pulse was 92. On the 10th and 11th the wound was dressed. On the 10th the temperature and pulse were 98·5° and 92 respectively and on the 11th 99·2° and 94 respectively. The bowels had not been moved since the injury though small doses of sulphate of magnesium and tincture of nux vomica had been given. A solution of cascara was now added. On the 12th the bowels acted three times freely. Seven sutures were removed. The temperature was 98·7° and the pulse was 94. On the 13th the temperature was 98·6° and the pulse was 94. The remaining sutures were removed. The wound was healed and quite firm. The patient was still on milk and beef-tea diet and taking quinine, cascara, and a solution of iron. On the 15th solid food was allowed for the first time. The temperature was 98° and the pulse was 90. The only further trouble with the case was caused by the inaction of the bowels, this causing a rise of temperature on the 21st to 100·4°. An enema and stronger aperients producing free action of the bowels brought it down, as on the 23rd it was only 99° and then went down below normal, and the bowels also acted daily. On the 29th the patient was allowed to sit up for a few hours. On August 10th she was up all day, moving about and doing light work.

Remarks.—This case is very satisfactory for antiseptic treatment, as every aseptic condition was absent in the house and in the patient's surroundings, and the dwelling about the last house one would have chosen to treat such a case in. The husband's position put a trained nurse out of reach and the nursing was done by neighbours coming in and doing what was required, I giving strict orders that under no circumstances were they to attempt to look at or interfere with the dressings and the wound. When seen on Jan. 14th, 1899, the patient said that she should not know that she had been injured and was working as usual.

Uppingham

TWO CASES OF INTUSSUSCEPTION IN INFANTS TREATED BY ABDOMINAL SECTION AND REDUCTION; RECOVERY.

BY JOHN BARLOW, M.D. EDIN., F.R.C.S. ENG.,
SURGEON TO, AND LECTURER ON CLINICAL SURGERY AT, GLASGOW ROYAL INFIRMARY.

THE history of the cases of intussusception narrated by Dr. David B. Lees and Mr. A. Quarry Silcock at the meeting of the Clinical Society of London on May 13th, 1898, the report of which and the subsequent discussion on this subject are contained in THE LANCET of May 21st, 1898, inclines me to believe that short reports of two cases of intussusception in young children in which I performed abdominal section with success may be of interest.

CASE 1.—A female infant, aged five months, was admitted into the Glasgow Royal Infirmary on Sept. 13th, 1896, at 3.30 A.M., suffering from abdominal pain and from sickness. The mother supplied the following history. The child had always been very healthy and plump. Her bowels had been moved on the day before admission; 18 hours before admission she began to cry and to draw up her legs and strain, but nothing came away from the rectum; eight hours before admission she vomited frequently, when the mother went to a chemist who gave a "powder" to relieve the vomiting; this, however, gave no relief. Two hours later a little slime and blood were passed by the bowel and on this being repeated the mother consulted Dr. Patrick, jun., of Bridgeton, who recognised the condition and ordered removal to the Glasgow Royal Infirmary. When I saw the child the pupils were slightly contracted, which was possibly the effect of the "powder," and there were abdominal uneasiness and blood around the anus. On palpating the abdomen there was no tension of the abdominal wall and a sausage-like tumour was easily made out on the right of, and slightly above, the level of the umbilicus. The mass was slightly moveable in all directions and pain was produced by compression. Under deep anæsthesia the mass was again examined and I attempted to reduce the intussusception by inflating the large intestine with hydrogen gas. As the gas was introduced the mass moved downwards and to the right and by manipulation I was conscious of its becoming smaller; it apparently diminished to one half of its original size. The inflation combined with manipulation was continued for a few minutes but the tumour remained. The abdomen was then opened in the middle line and the affected area of bowel was easily found and brought near to the abdominal wound. The intussusception was of the ileo-colic variety. Reduction was effected by gentle traction on the ileum combined with compression of the mass within the colon towards the ileum, but the serous portion of the invaginated bowel was red and rough for a distance of two inches and here adhesions were gently broken down. The wall of the invaginated portion was thickened. The margins of the abdominal wound were brought together by a row of sutures of catgut through the peritoneum, a second row through the aponeuroses, and a third row through the skin. The usual dressings were applied. There were two points to be noted during the operation: (1) the small space available between the umbilicus and pubes in a fat child aged five months; and (2) that while there was distension of the small intestine generally the portion of the ileum adjoining the intussusception for a distance of a foot was empty, ribbon-like in form, and with its muscular coat in a condition of contraction. It seemed to me that the active peristalsis, however induced, may have been the cause of the disease. I afterwards learned that the mother who suckled the child had been eating quantities of fruit on Sept. 12th and this may have been the intestinal irritant in the case of the child.

There is not much to add about the history of the case after operation. One minim of tincture of opium was given when the anæsthesia passed off and a teaspoonful of milk was administered every hour. This amount of milk did not satisfy the child, and on the day following the operation and just before the time of my visit the catgut stitches gave way during a spell of crying and struggling, and when I saw the child many coils of small intestine were outside the abdominal wound and through the promptitude of the nurse covered with a sponge wrung out of hot solution of carbolic acid. Chloroform was given and the intestine was returned, and this time eight silkworm gut sutures were passed through all the layers of the abdominal wall and the edges of the wound were approximated. The mother was allowed to suckle the child and she appeared comfortable. Two days later I gave the mother castor oil and within 24 hours there were several evacuations from the bowels of the child. The sutures were removed on the tenth day, and the child left the hospital quite well two days later, or 12 days after the operation.

CASE 2.—A male infant, aged seven months, was admitted under my care into the Glasgow Royal Infirmary at 11 P.M. on April 28th, 1893, the boy having been seen during the afternoon by Dr. Robert Grieve of Glasgow. The mother stated that she noticed something to be wrong with the child about 2 P.M. The child who was usually contented and happy suddenly screamed out and the screams were repeated at short intervals of time. Vomiting occurred within an hour and subsequently there were diarrhœa and the passage of blood and slime by the bowel. The child was suckled by the mother and had nothing except the mother's milk and the mother had not, so far as could be ascertained, taken any unusual article of food. On admission the child was evidently suffering from abdominal pain coming on at intervals of a minute, but there was no collapse. Palpation of the abdomen detected a sausage-shaped tumour slightly above the level of the umbilicus and extending to the left of the middle line. During the examination and in one of the paroxysms of pain a mixture of blood and slime passed through the anus. Chloroform was given and a further examination was made. An attempt at reduction by manipulation was unsuccessful and the abdomen was therefore opened in the middle line, when a brownish-coloured mass of large intestine presented. The swelling was about eight inches in length, extending from two inches to the left of the umbilicus and curving downwards and to the right into the right iliac fossa. In order to effect reduction by a combination of traction on the ileum with compression of the colon beginning below the intussusception and extending toward the ileum it was necessary to enlarge the wound in the abdominal wall to a point an inch above the umbilicus and with this increased space for manipulation reduction was effected. The cæcum and vermiform appendix were found reddened and the walls thickened and roughened, and upon their reduction some flaky lymph was seen. The small intestine was distended up to a point about a foot distant from the intussusceptum, but below this the gut was ribbon-like in form and the muscular coat was in a state of contraction. Silkworm gut sutures were employed, being passed through all the layers of the abdominal walls. When I saw the child next day fæces mixed with a little blood had been passed. The child had been sleeping and there was no pain or sickness. On May 1st the site of the wound was examined owing to a slight fouling of the dressing with urine, but union had occurred. The sutures were removed a week later and the child left the infirmary well 19 days after operation. He had been restless for three days owing to the eruption of the incisor teeth.

It will be noted that in Case 1 when the child was under the full influence of the anæsthetic I employed inflation with hydrogen gas without success. I believe, however, that had the abdominal wall not been completely relaxed I might have regarded the reduction as complete. The examination of the cæcum, which formed part of the intussusceptum, inclines me to believe that to have produced sufficient pressure within the colon to have broken down the adhesions would have been attended with risk of perforation near the cæcum or elsewhere. In the second case I did not attempt inflation as the amount of bowel invaginated was obviously extensive and the results of inflation are necessarily uncertain in such cases and the process is not unattended with danger. By performing abdominal section it is not difficult to determine whether reduction can take place by combining gentle traction on the ileum with compression of the intussusceptum—a combination not attainable by the use of inflation or of enemata—and the operator may, if necessary, repair perforations or perform resection.

Glasgow.

A NEW METHOD OF TREATMENT FOR PROLAPSE OF THE UTERUS WITH NOTES OF 10 CASES OF PROCIDENTIA.

BY J. INGLIS PARSONS, M.D. DURH.,
M.R.C.P. LOND., &C.,
PHYSICIAN TO THE CHELSEA HOSPITAL FOR WOMEN.

PROLAPSUS UTERI is one of the reproaches of gynæcology. It is very common among poor working women, a class who can least afford to be incapacitated when many mouths are probably dependent upon their efforts. No further excuse than this is needed for investigation into this subject. In my preliminary notice[1] I described the relation which evolution appeared to bear as a factor in the causation of this complaint. We have only to consider the mechanical disadvantage at which the ligaments of the uterus are placed in the erect position and the excellent support which they afford in the quadrupedal position to at once understand that woman lost almost as much as man gained by the change from the latter to the former. In the erect position the heavy end of the uterus is raised up instead of hanging down and directly it passes the perpendicular gravity helps to retrovert it. In the quadrupedal position, the vagina becomes a strong suspensory ligament, instead of a weak supporting column, while the abdominal wall bears its proper share in supporting the contents of the abdomen and prevents undue straining of the pelvic floor.

The disadvantages of the erect position are partly counterbalanced by the curve between the brim and the outlet of the human pelvis as compared with the almost straight line found in the quadrupeds. Natural selection during many thousands of years has achieved a great deal and produced in single women a type which in the majority is able to undergo even severe muscular exertion during the prime of life without prolapse occurring. But the margin of security in many cases is small. Any great strain or relaxation of the pelvic structures from ill-health or advancing age, even in single women, is liable to be followed by prolapse and even procidentia in some cases. As soon as pregnancy has occurred the liability is greatly increased owing to the probability of a disturbance in the equilibrium of the forces within the pelvis. There appear to be three main causes of prolapse: (1) failure of the uterine ligaments; (2) laceration, weakness, and relaxation of the pelvic floor; and (3) increase in weight of the uterus. The part played by each of these causes varies very much in different individuals.

The uterine ligaments may give way without any relaxation of the pelvic floor, or increase in size of the uterus. I described a case of this kind occurring in a single woman, aged 35 years, where procidentia occurred and ruptured an intact hymen, although the uterus was normal in size and the pelvic floor was perfect. In contrast to this I have recently operated on a patient, aged 43 years, with complete rupture of the perineum extending through the sphincter ani which occurred 10 years ago. During all that time no descent of the uterus followed in spite of the great imperfection in the pelvic floor, showing that the ligaments alone are capable of sustaining the uterus in some cases, but if they are defective even a good pelvic floor with an intact hymen will not prevent procidentia. In other cases the ligaments may be just strong enough to keep up the uterus, provided that they are assisted by a normal pelvic floor. Under these conditions if rupture of the perineum occurs and is left unrepaired prolapse will soon begin. Or the fault will be found in the increased weight of the uterus from sub-involution or other cause. Here again the ligaments may be just strong enough to sustain the normal uterine weight, but as soon as it is increased they commence to stretch. When the uterus has been reduced to its proper size by appropriate treatment the patient recovers and can do without a pessary. But very large numbers of cases occur where treatment is not so simple. In the same patient all these causes may be at work. Combined with an enlarged uterus we often find in procidentia a weak and imperfect pelvic floor with incapable stretched ligaments. The uterus cannot always be reduced to its normal weight. When the general health is deteriorated the perineum stretches again after repair and the whole pelvic floor loses tone and partly gives way. While in many instances no pessary can be retained procidentia then occurs and the poor woman becomes a useless member of the community. These cases are not uncommon, there are thousands of them.

For several years I gave the operation of colpoperineorrhaphy a good trial, with considerable success so far as the operation was concerned. The perineum and vagina by this means can be reduced to a virginal form. If the patients are not allowed to get about for two months the new tissues have time to consolidate and in about two-thirds of the cases very little stretching takes place. When the fault lies with the pelvic floor the patient is greatly improved and is often restored to health, but in time the perineum without the help of the ligaments is unable to sustain the whole of the downward pressure and gradually gives way. In operations on the pelvic floor the chief structures concerned in holding up the uterus—viz., the ligaments—are left untouched. The method of treatment which I now bring forward is an attempt to strengthen the broad ligaments by appropriate means. This seems to me to be a more rational proceeding than attempting to form an unnatural ligament by attaching the fundus to the abdominal wall.

Let us consider prolapse of the uterus as a dislocation and compare it with what takes place when dislocation in an ordinary joint—say the ankle—occurs. In the latter case the sudden wrench which produces the dislocation causes laceration or stretching of the ligaments and bruising of the surrounding tissues. *The irritation thus set up produces* an effusion of lymph which repairs the damage and new adhesions form which strengthen the weakened ligaments. In many cases nature does too much, although she sometimes fails to do enough. Now, when prolapse of the uterus occurs, the dislocation in nearly every case is so gradual and is spread over so long a period of time that the surrounding tissues are able to accommodate themselves. There is not sufficient injury to set up irritation and no effusion of lymph takes place to strengthen the overstretched ligaments. After thinking it over I could see no reason why we should not take advantage of this physiological function and supply the stimulus necessary by the injection of a suitable fluid into the cellular tissue of the broad ligaments and thus force nature to do her proper work. Moreover, it is common knowledge that after an attack of pelvic cellulitis there generally remain some adhesions sufficient to prevent a prolapse. It might be urged that there is a risk in setting up reparative action. In answer to that I would say that it depends upon how it is done. If all germs are excluded the reaction set up is proportionate to the stimulus applied, the only variations being due to age and idiosyncrasy. I suggested this in my first paper, and I have since found in practice that it is correct. That inflammation is a disease, as our forefathers thought, cannot now be accepted. In the light of modern research we must regard it as a reparative and protective process. No hard-and-fast line can be drawn between the effusion of lymph for the repair of a mechanical injury and the acute inflammatory process produced by toxins; they are both gradations of the same protective power. Undoubtedly inflammation may be so violent as to cause local injury, but this very violence will locally block the entry of bacteria into the general system or by suppuration get rid of a foreign body harmful to the tissues and life is saved at the expense of some local damage.] Like the structure of the body the phenomena of inflammation have in all probability been gradually evolved with other physiological functions by natural selection in the long distant past before man had learnt the use of a stone axe or even left the ranks of the quadrupeds. And just as the body produced by natural selection is in some respects imperfect in structure so also is inflammation not altogether perfect as a reparative and protective process, but sometimes it requires to be controlled by the physician and either curbed or spurred according to circumstances.

As an instance of the protective power of inflammation may be mentioned the gluing together of surfaces round ulcerations in the stomach and intestines by which the general cavity of the peritoneum is shut off. This is only an example of what in fact may occur in any part of the body when an injury calls for its manifestation. For the surgeon to use inflammation as a reparative process under his own control is no new principle; it has been extensively used for chronic hydrocele of the tunica vaginalis and in stimulating the ends of an ununited fracture of bone by driving in ivory pegs or by other means. I fail at present to see any reason why this reparative process should not be used by the gynæcologist to strengthen the broad ligaments and so help to keep up the uterus. It is not meant to supersede all other treatment, but when other means have failed and as an adjunct to what has already been done. When the perineum is ruptured it should be sown up and all other measures which are likely to restore the tone of the pelvic floor should be used. If the uterus is enlarged it should when possible be reduced to its normal size, while a great many cases can be restored to health by rest and other simple means.

---

[1] Brit. Med. Jour., Oct. 23rd, 1897.

The anatomy of the broad ligaments requires careful consideration. Under normal conditions they are bounded anteriorly and posteriorly by two folds of peritoneum which leave the sides of the uterus and pass outwards and somewhat backwards to the sides of the pelvis. Above are the Fallopian tube and the junction of the two peritoneal folds; below are the pelvic floor and the vaginal fornix; on the inner side is the uterus with its artery and veins, and on the outer the wall of the true pelvis with the obturator internus. The space thus enclosed is filled with cellular tissue, lymphatics, and blood-vessels. This cellular tissue—called by Virchow the parametric connective tissue—is of the greatest importance, for its presence renders this treatment possible. It is most dense near the uterus and when followed outwards continues on to the upper part of the side wall of the true pelvis. It is more or less continuous with that in the iliac fossa and under the peritoneum at its different points of reflection in the pelvis (Hart and Barbour). In the normal woman able to go through a good deal of physical exertion without any ill result a band can be felt through the vaginal fornix on each side of the uterus in the broad ligament between the uterus and the pelvic wall.

Dr. J. C. Webster, speaking of the broad ligaments, tells us:[2] "The peritoneal covering is of very little practical importance in supporting the uterus. Within this covering is fibro-muscular and elastic tissue which can be traced as bands in several places running from the uterus to the pelvic walls. If the slightest downward pressure is made on the uterus in the cadaver it is found that a line of resistance is formed in the broad ligament running from the cervix upwards and outwards towards its upper parietal attachment." Sir William Turner says that they act as lateral ligaments for the uterus. In the operation of vaginal extirpation of the uterus after the organ has been separated from its vesical and vaginal connexions, although the vagina be distended as widely as possible the uterus does not tend to fall down, but is kept in position by its ligamentous attachments. When the uterus is pulled down and then let go it is instantly drawn up again. Dr. Savage[3] considers the broad ligaments to be of great importance in holding up the uterus. All this evidence gives strong support to the treatment brought forward. The uterine artery leaves the pelvic wall just above the ischial spine, but continues to descend downwards and inwards towards the cervix; it then makes a bend upwards, crosses the ureter, and reaches the uterus just above its junction with the vagina. It runs up the side of this organ in the folds of the broad ligaments and finally anastomoses with the ovarian artery. The uterine veins accompany it and form a plexus along the side of the uterus. To look at some of the plates in the text-books one would think that the whole of the broad ligament was one mass of veins, but this is by no means the case. If the broad ligament be opened up in its outer two-thirds by an incision through the vaginal wall, as I had to do in Case 5, it will be found that there are no veins to be seen and that the vaginal incision and also a deeper one into the cellular tissue causes practically no bleeding. The ureter on entering the pelvis crosses the common iliac near its bifurcation and runs downwards and forwards in front of the anterior branch of the internal iliac, passes obliquely along the base of the broad ligament, and is crossed to the outside by the uterine artery. At the level of the internal os it turns forward and at a distance of half an inch from it runs along the side of the vagina, finally bending over it so as to enter the junction between the vagina and the bladder. There is therefore a space in the outer two-thirds of the broad ligaments free from any structure of importance except the cellular tissue. If a point then be chosen in the vagina from about three-quarters of an inch to an inch from its junction to the cervix and on a level with the external os and a needle is inserted to a depth of one inch in a direction parallel to the side of the uterus the point will be in the cellular tissue about the middle of the broad ligament and quite clear of any structure which should be avoided.

It was a long time before I could make up my mind as to the best means for producing an effusion of lymph. The treatment of hydrocele by injections was not much of a guide because cellular tissue is very different from a serous membrane. The strength of solutions used to obtain adhesions of the tunica vaginalis would cause sloughing of cellular tissue. At the suggestion of my friend Dr. Aikman of Guernsey I tried quinine. It has many advantages, being strongly antiseptic, more tonic than poisonous to the general system, and at the same time acting as a local irritant. There can be very little doubt that after the injection the quinine is deposited. If any absorption takes place it must be very slowly for none of the patients have ever had the slightest sign of the usual symptoms which follow the administration of a large dose of quinine by the mouth although as much as 16 grains has been injected at a sitting. Quite possibly other reagents would do as well or perhaps better. As I find quinine answers the purpose I have not tried anything else.

Operation.—The patient is placed in the lithotomy position. The vagina is thoroughly douched and rendered as much aseptic as possible. The perineum is then retracted with either Auvard's or Sims's speculum. Another retractor is then used to hold up the anterior wall of the vagina if necessary. The lateral walls are then exposed. The uterus is held with one hand as nearly as possible in its normal position by a probe passed into its interior. With the other hand the injections are made on each side through the vaginal wall into both broad ligaments on a level with the external os and from about three-quarters of an inch to an inch from the junction of the vagina to the cervix. After the syringe and speculum have been withdrawn it is necessary to keep the uterus up with a cup and stem pessary held in position by four tapes tied round the waist. This is left in position for three or four days and is then removed. A special syringe with a long, thin nozzle is a great convenience because it does not obstruct the light and it enables the operator to see that the needle-point pierces the vaginal wall at the right point. The needle should not be more than an inch in length or much thicker than a hypodermic needle in order that the puncture may close quickly.

CASE 1.—The patient was a woman, aged 61 years, who had been suffering from prolapse for seven years and from procidentia for four months, with extensive ulceration of the cervix from friction. One injection was given in June, 1897, into each broad ligament. At the end of two months she left the hospital feeling very well and free from pain. When she stood up and strained as much as possible she was unable to cause any prolapse of the uterus; a slight thickening could be felt in each fornix, while the normal mobility of the uterus was but little if at all impaired. The vaginal walls bulged slightly at the vulva when she strained, but much less than before as the uterus was held up. At the end of six months (Jan. 3rd, 1898) I examined her and as the improvement was maintained I determined to go on with other cases. On Dec. 12th, 1898, I saw this patient again and examined her—one year and six months after the operation. She had been at work all this time. When she stands and bears down as much as possible there is no descent of the uterus. She feels very well and I was very pleased with the improvement in the poor woman's condition.

The following are the abbreviated notes of the other nine cases.

CASE 2 (hospital case).—The patient was a woman, aged 37 years. She was admitted to hospital on Jan. 24th, 1898. She had had two children. Prolapse had been present for 10 years and procidentia for three years. The uterus was enlarged. There was profuse discharge. The pelvic floor was weak and the perineum was stretched. She was unable to hold a pessary. She had incontinence of urine at times. On Feb. 3rd an injection of 20 minims of a solution of quinine (10 grains to the drachm) was given. On the 6th the uterus was held up by effusion. There was no rise in temperature. In April, 1898, there was some stretching of the new tissue and the uterus descended about an inch from the normal. In June, 1898, the cervix came down to the vulva to come in for a second injection. On July 11th operation was performed without any anæsthesia; quinine solution (one in five) was injected into both broad ligaments. On July 20th effusion was good. The uterus was well held. The temperature was normal. In October the uterus kept up in good position. She had been at work.

[2] Researches on Female Pelvic Anatomy, p. 88.

[3] Anatomical Illustrations of the Surgery of the Female Pelvic Organs.

Case 3 (hospital case).—A woman, aged 39 years, was admitted to hospital on Jan. 24th, 1898. She had had eight children. Prolapse had been present for two years and procidentia for one month. She had severe pain in the back. She could not retain a pessary. Incontinence of urine was present at times; the discharge was profuse. She had a short perineum. On Feb. 10th an injection of 25 minims of solution of quinine (one in six) was given. Her temperature was normal. There was good effusion; the uterus was well held up. The patient wrote on June 22nd: "I am at work in a laundry, so cannot come to see you. I am better than I ever thought to have been, but not so well as I should like to be." In December, 1898, the uterus was in good position. There was no prolapse. She had been hard at work without a pessary.

Case 4 (hospital patient).—A woman, aged 44 years, was admitted to hospital in February, 1898. She had had five children. She had had severe prolapse and procidentia for 15 years. She could not retain a pessary. There was incontinence of urine at times. The uterus was enlarged and heavy. The pelvic floor and vagina were very weak and relaxed. On Feb. 24th an injection of 25 minims of solution (one in six) was given. Her temperature was 100° F. for two days and then normal. In June, 1898, the broad ligaments were not strong enough; the uterus still descended. On August 4th a second injection of 30 minims of solution (one in five) was given, the patient being under ether. On the 11th effusion was good. There was no rise in temperature. On the 25th colpoperineorrhaphy was performed. There was good union in September. In December, 1893, there had been no return of the procidentia. *The uterus kept up fairly well.* The patient wears a pessary.

Case 5 (hospital case).—The patient was a woman, aged 29 years. She had had but one child. She was admitted to hospital on March 4th, 1898. Procidentia had been present for 18 months after her confinement, with incontinence of urine. She had tried seven different pessaries. The pelvic floor and vagina were fairly good. On March 10th an injection of 25 minims of solution (10 grains to the drachm) was given. The needle broke off in the left broad ligament. It was cut down upon and removed. On March 17th the sutures were removed and the wound healed. There was no pain or discharge and no rise in temperature. On June 22nd the uterus was in a very good position. On standing and straining there was no descent whatever. The patient felt very well. No pessary was required.

Case 6 (hospital case).—The patient was a woman, aged 46 years. She had had nine children. Prolapse had been present for seven years. Procidentia began four years ago. The perineum had been repaired three and a half years ago; it was better for 12 months. Procidentia recurred 12 months ago. The pelvic floor and vagina were weak and lax. The *left broad ligament was fairly strong.* The right gave way completely. She had an irritable bladder. On March 21st, 1898, an injection of 25 minims solution (10 grains to the drachm) was given with the patient under ether. A second injection was given on March 31st of the right broad ligament. There was sufficient effusion. The uterus was well held up. There was no trouble with the bladder now. She had slight pain in the left side. There was no rise in temperature. On May 19th the uterus kept up well. On June 22nd the patient was going on well; there had been no prolapse. No pessary was required.

Case 7 (hospital case).—The patient was a woman, aged 55 years. Prolapse had been present for 12 months and procidentia for four months. She could not retain a pessary. The pelvic floor and vagina were weak and very distensible. There was a yellow discharge. On March 17th an injection of 25 minims of solution (10 grains to the drachm) was given. On April 4th a second injection was given as before. The uterus was well held up. There was less effusion than in other cases. The temperature, after the first injection, rose to from 101° to 102° F. the day following. It was normal after the second injection. There was no pain. She was discharged on April 16th. On June 16th she felt very well and was quite comfortable. She had been at work for a month. On examination the uterus was in position and was well held up by the bands on each side. On Dec. 12th, 1898, the uterus was in good position. There had been no descent. No pessary was required.

Case 8 (hospital case).—A woman, aged 51 years, was admitted into hospital on March 18. She had had 10 children. Prolapse had been present for 10 years and procidentia for three years. She could not retain any pessary. There was profuse offensive discharge. She could not micturate when the uterus was down. The family history was good. The pelvic floor and vagina were very lax. On March 24th 25 minims of solution (10 grains to the drachm) were injected with the patient under ether. There was less effusion than usual. On April 14th an injection of 30 minims (10 grains to the drachm) was given, cocaine anæsthesia being employed. On the 25th an injection of 40 minims of the same solution was given. There was a fair amount of effusion. The temperature rose to 100° F. for three days after the first injection; there was no rise with the second and third. On June 22nd the uterus kept up well. There was slight descent on straining and some cystocele; the patient felt very much better and had been doing her work. She wore a ring pessary. In December she was very well; there had been no prolapse.

Case 9 (private case).—The patient was a woman, aged 66 years, who had been under the care of Dr. Aikman of Guernsey. She had had one child. Prolapse had been present for 12 years and *procidentia for six years. She could* not retain a pessary. There had been retention of the urine with procidentia. On April 8th, 1898, chloroform was administered by Dr. Webster and with Dr. Aikman's assistance 30 minims of solution (12 grains to the drachm) were injected into each broad ligament. There was no rise of temperature. The uterus was held up. Dr. Aikman wrote on June 25th: "I saw the patient at the end of her day's work. The fixation of the uterus is perfect and she is most grateful. She has been a great deal about and is doing all her housework. It is certain she did not take the full amount of rest which was advised for her, but that is only further testimony to the success of the treatment." On Dec. 10th, 1898, Dr. Aikman wrote: "The patient is quite well. She goes about without any inconvenience and is profoundly grateful to you."

Case 10 (hospital case).—A woman, aged 65 years, came into hospital on April 23rd, 1898. She had had a family of 10 and five miscarriages. Prolapse had been present for 36 years and procidentia for 25 years. Incontinence and retention of urine were frequent. The whole of the pelvic floor gave way. She could not retain a pessary. On April 28th under ether 40 minims of solution (12 grains to the drachm) were injected. There was very little effusion. On May 9th (cocaine anæsthesia) 35 minims of the same solution were injected. Effusion was more marked. On May 26th (cocaine anæsthesia) 40 minims of the same solution were injected. The temperature after the last injection rose to 102·5° F. and fell to normal on the fourth day. Effusion was satisfactory. The slight pain and tenderness in the pelvis disappeared in three days. On June 13th she had been up for three days and felt nice and comfortable. On June 21st she went to a convalescent home. The uterus was in a very good position; there was no prolapse whatever. The patient wears a ring pessary. In December she was very well and had had no prolapse, remaining the same in January, 1899.

Remarks.—In all these cases prolapse had existed for years, and in Case 10 actual procidentia for twenty-five years. All other treatment having been tried without success they may be considered as good test cases and much worse than the average woman with prolapse condemned to wear a pessary for the term of her natural life. In most of the cases an anæsthetic was given. As the operation does not take more than five or 10 minutes it is not necessary but preferable. In lieu of that, two tampons soaked in a 20 per cent. solution of cocaine placed one in each fornix for a few minutes prevented the insertion of the needle from being felt. When the quinine solution was injected it sometimes caused no pain, in others slight pain. The legs must be held immoveable in a Clover's crutch or other arrangement. The object of inserting a pessary for a few days after the operation is to make sure that when the effusion does take place it will hold the uterus in a good and not in a bad position. After the operation most of the patients have practically no pain. There is a slight aching in the pelvis for a day or two. At the end of a few days the pessary is removed. On examination it is then found that the uterus is held up and when the patient strains as much as possible no prolapse occurs. In both fornices some effusion in both broad ligaments can be felt with a little tenderness. The amount of effusion will depend on the personal reaction of the individual and the strength and amount of the solution injected. The swelling is not hard like a parametritis, nor is it at all extensive, but feels more like a band in most cases, passing from the uterus to the wall of the pelvis. It is firm and resilient. The uterus is held in position, not fixed; but still it has mobility. In Cases 8 and 10 the amount of effusion was much less than in the others. Both of them were old women with an excellent family history and large families of their own, and with the exception of the procidentia enjoyed good health. They were both thin and wiry, but gave the impression of being aged prematurely. The effusion also felt more localised in one spot and less of a band than in the others. On this account, and because the procidentia was more marked the injections were repeated. At first enough was not done for Cases 2 and 4. The reduction in the strength of the solution from that used in the first case was too great (from 15 to 10 grs.) and more than one injection was required. It takes some experience to know how much effusion is necessary in each case to afford permanent support. The number of injections must be proportioned to the exigencies of the case. Sometimes very little may be sufficient to restore the balance; in others, such as Case 10 where the procidentia had existed for 25 years and where the perineum had given way altogether a great deal of strengthening may be necessary to enable the ligaments to do their own work as well as that of the pelvic floor. There is no need for any rise of temperature to take place. In six cases (Cases 2, 3, 5, 6, 9, and 11) the temperature remained normal. Two cases touched 100° F.; only one, Case 10, reached 102·5° after one only of three injections. The patients seem to do just as well whether they have a slight rise of temperature or not. In fact I do not find any difference in results. There was no suppuration in any of these nine cases, although it has occurred in a recent case which will be published in its turn with my next series. The patient in the first case felt no ill-effects from slight suppuration, while she has been much benefited by the uterus keeping up. Nearly all these patients might have got up at the end of a week so far as the operation was concerned. But the object in view was to obtain organisation of the lymph so as to give permanent support in the broad ligaments.

As I stated in my preliminary notice we do not at present know why absorption of an exudation should take place in one case and organisation in another. Empiricism helps us by the observation of injuries to joints. A severe sprain to a healthy man or woman causes swelling from the effusion of lymph thrown out around the joint and after the subsidence of the inflammatory reaction adhesions begin to form and in many cases more than are required. To combat this passive movements and massage are resorted to. On the other hand, the longer the joint is kept in a splint and at rest the greater the number of adhesions which will form. If we apply this lesson to the pelvis we at once see the necessity of keeping the patient as nearly in a splint as possible and that is in bed for a month or two, not only to promote organisation of the lymph thrown out but also to prevent any strain until it is strong enough to bear it. The risk does not appear to be very great, all the patients having recovered from the operation. I mentioned in my first paper that one might expect considerable disturbance in the normal relations of the pelvic organs as a result of procidentia even after the uterus had been reduced and kept in place for a few days or a week and the needle under these circumstances might pierce some structure which we would wish to avoid. This, I think, would be more likely to occur in the worst cases of procidentia, but then the worse the case the more justification for running some risk on account of the helpless condition of the patient. As the needle is barely larger than a hypodermic needle it would probably not do much harm if it did pierce other structures than those intended. Then the solution of quinine is antiseptic. Dr. Anna[4] found that the injection of the bichloride of quinine into a vein or artery caused no coagulation and that there was no danger attached to it. A complication did occur in Case 5 which I had not expected. The needle which had become corroded by the quinine solution broke off in the left broad ligament. An incision was made through the vaginal wall over the point of insertion and again into the cellular tissue and the needle was extracted. No veins were to be seen and there was practically no bleeding, so I do not think there need be much fear of a hæmatoma from the injections. The incision healed by primary union and the patient did admirably.

We may, I think, compare procidentia with fibroma of the uterus in that it is rarely although sometimes a fatal disease and one which incapacitates the patient from the duties of life. If, then, a mortality of from 10 to 15 per cent. is justified in the surgical treatment of fibromata we are certainly justified in running some risk in the treatment of procidentia because up to the present these cases have been given up as incurable. By holding the uterus up in good position cystocele and rectocele in rather more than half the cases disappeared, and in the rest were greatly diminished. When there is still some bulging of the vaginal walls in spite of the uterus being kept up I find that a ring pessary does away with it and makes the patient quite comfortable.

Queen street, Mayfair, W.

FURTHER REMARKS ON THE OPEN METHOD OF ADMINISTERING NITROUS OXIDE GAS.

BY GEORGE FLUX, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.,

ANÆSTHETIST TO THE GREAT NORTHERN CENTRAL HOSPITAL AND TO THE BRITISH LYING-IN HOSPITAL; ASSISTANT ANÆSTHETIST TO THE DENTAL HOSPITAL OF LONDON; LATE ANÆSTHETIST TO THE NATIONAL DENTAL HOSPITAL.

SINCE first drawing attention in THE LANCET of Oct. 8th, 1898, to a plan which I had devised for inducing anæsthesia with nitrous oxide gas with an open inhaler, avoiding the use of valves or closed face piece, and making use of a normal atmospheric pressure, I have been regularly employing this method both in my private practice and in hospitals and so far have found that further experience bears out my opinion of its practicability and efficiency and also as to the increased comfort which it secures to the patient. In a consecutive series of 250 unselected cases of which I have kept notes the results have been almost uniformly satisfactory.

It has been repeatedly demonstrated that with an accurately fitting closed inhaler the violent physiological disturbance of the patient can be much modified by the *intentional* admission of a little air or oxygen. The doctrine that a face-piece when applied must be air-tight has, in my opinion, been a stumbling-block to progress in the administration of nitrous oxide gas for many years, since it begets the conclusion that to admit air must interfere with the effect of the gas. I venture to think that this conclusion is erroneous and that the difficulty with an ill-fitting face-piece depends not so much upon the ingress of air as upon the very rapid escape of the heavier nitrous oxide gas. Letting air in is by no means the same thing as letting the gas out. In the former case the quantity of gas available for the patient is not necessarily diminished; in the latter it is very much so, especially if the escape of gas is very free, as often happens when the patient has much hair upon the face. Under the circumstances, unless the pressure of gas is very materially increased to compensate for what is lost by leakage, the patient will not be able to absorb a sufficient quantity to render him completely anæsthetic, although he inspires enough to render him excited and unruly. By the use of an inhaler which is completely open to the air at the top and into which the gas is allowed to fall from the end of a supply-pipe held over it the full anæsthetic effects of nitrous oxide gas can be obtained. If the inhaler is accurately applied to the face there cannot be any escape of gas, unless due to overflow resulting from too free a supply. The weight of the gas prevents escape upwards and unless leakage is permitted between the margins of the inhaler and the face there can be no escape downwards. If an ordinary pint pot is filled with nitrous oxide overnight and left uncovered and undisturbed a considerable proportion of the gas will still be there in the morning. A mouse placed at the bottom of an unclosed vessel into which anæsthetic for five and a half hours and on removal recovered completely in one minute. The gas when given in the open inhaler being freely exposed to the air and mixed with it can only be inhaled at the atmospheric pressure and the pressure can neither be increased by an excess of gas nor lowered by a reduced supply. The gas as it falls into the inhaler by its own weight is warmed by the breath of the patient and by the surrounding atmosphere—an important point when the cold produced by the rapid evaporation of the gas on leaving the cylinders is remembered. From a hygienic standpoint there is a very wide difference between an inhaler which is open to the air and unconnected with anything and one which is completely shut off from the surrounding air and is connected by tubes and valves to indiarubber bags, all of which are admittedly most difficult to keep pure and into and out of which both the healthy and the unhealthy must breathe. It will be seen therefore that with the open inhaler several conditions are absent which are present to the discomfort and disturbance of the patient when a closely-fitting air-excluding mask is used—viz., the cutting off of the air-supply, breathing under artificial pressures, the breathing of cold gas, the possibility of tuberculous infection, and minor discomforts, such as the smell of the gas bag, the whistling of the gas, and the noise of the valves.

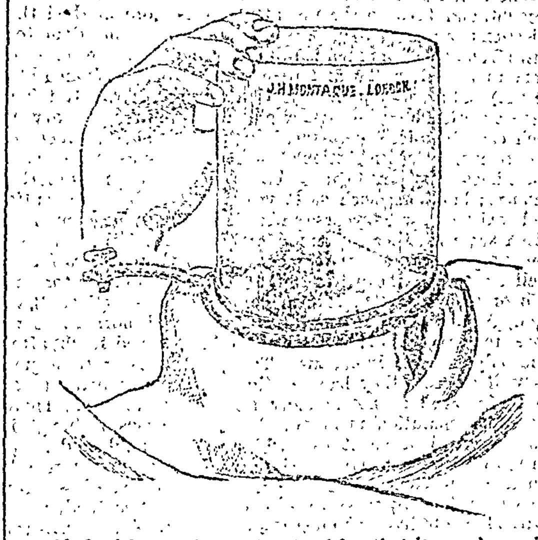
The effects produced upon the patient when gas is given with the open inhaler are generally as follows. After the first few breaths the agitation caused by apprehension subsides; the patient assumes a sleepy appearance and in from five to 10 seconds is unconscious; the breathing becomes steady and tranquil; and by the end of from 50 to 80 seconds the patient is anæsthetic, with the muscles relaxed and the reflexes abolished. The only visible sign is the change from a condition of wakefulness to sleep which is so tranquil that onlookers who have not previously seen this method employed can scarcely believe that the patient is ready for operation. Movement seldom occurs before the commencement of return to consciousness which is usually gradual. No excitement, stertor, lividity, struggling, or convulsive movements occur. In no case of the above-mentioned series has it been necessary to use force to restrain the patient during or after the exhibition of the anæsthetic. Occasional instances of screaming have occurred on recovery, the patients being nervous women, weak and ill, who had previously screamed under other methods. The symptoms of asphyxia which so frequently accompany the use of gas anæsthesia when an accurately-fitting, air-excluding mask *is used are completely absent when this method is* employed.

I have asked several well-known physicians to watch cases for me and although the administrations have lasted up to periods of 11 minutes they have observed no change in the patients beyond a slight increase of pulse-rate during the first few moments of inhalation, the pulse and respiration soon settle down to a quiet, unchanging rhythm. It was impossible to determine, however, whether the initial slight increase in pulse-rate was due to agitation or to the anæsthetic. The return to consciousness when the patient is not disturbed is placid and tranquil; he quietly opens his eyes, looks about him, realises his position, and behaves according to his temperament. If the operation is continued beyond the duration of true anæsthesia signs of apparent discomfort will appear before clear consciousness is established. The most constant early sign of returning sensibility is a slight "*screwing up*" of the eyelids, followed by slow, vague movements of the limbs which will quickly, but not abruptly, become defensive if the operation is continued.

In spite of many experiments as to size and shape of face-pieces and of variations in the manner of regulating the gas-supply inseparable from attempts to decide upon the most practical procedure, complaints of unpleasant after-effects have been few and far between and even when present have been of very transient nature. In several cases where the operations have lasted several minutes and the patients have been under constant competent observation both before and after no subsequent ill-effects have been observed. In one instance a lady was under gas by this method for four and a half minutes for removal of a Meibomian cyst and she felt no subsequent disturbance; she had taken gas on several previous occasions and had always been sick for three days.

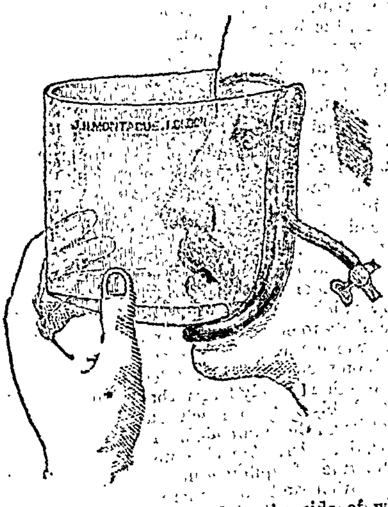
Up to the time of my first communication on this subject I had simply used as an open inhaler some textile fabric—e.g., a napkin or towel folded and adapted to the face in such a manner that the nose and mouth were partially enclosed in a more or less cup-shaped cavity completely open at the top. As an extemporised face-piece is not always convenient I have had some more permanent inhalers constructed which give very satisfactory results. These inhalers are made in two forms, one cylindrical in shape for use when the patient is lying down (Fig. 1); the other somewhat cup-shaped when in position for use when the patient is sitting up (Fig. 2). A glance at the accompanying sketches will show the appearance of the face-pieces when in use. The material used in their construction is clear, thin celluloid—a substance which is at once light, transparent, and very pliable; it is non-absorbent and can be easily and rapidly cleansed. The somewhat cylindrical inhaler (Fig. 1) is completely open at either end and is flattened from side to side; the upper end is straight, but the lower is curved and provided with an air-cushion in order that it can be easily fitted over the nose and chin and rest evenly upon the face of the patient. The long diameter of this inhaler should correspond to the distance between the bridge of the patient's nose to midway between the lower lip and the point of the chin and the narrow diameter to the extreme width of the patient's mouth. The depth of the inhaler should be equal to the sum of the long and narrow diameters. The other inhaler (Fig. 2) is formed of a wide piece of celluloid bent so as to form a semicircle, into the side of which the face looks. The space thus formed is freely open at the top, but closed at the bottom by a celluloid floor which is continuous with the sides; the floor is curved downwards from side to side in order to facilitate cleanliness and to render it more comfortable to the patient. The free margin of the floor is curved in order that it may fit the face of the patient

FIG. 1.



J.H.MONTAGUE. LONDON.

FIG. 2.



when applied either below the lower or above the upper lip The sides of the inhaler reach from the eyes to the upper part of the chin, and the opening for the face is sufficiently wide to clear the orbits on either side The projection forward in the case of an adult is from three to three and a half inches The margins where the inhaler comes in contact with the face are suitably shaped and are furnished with a soft air cushion in order that accurate adaptation can be secured and loss of gas by leakage prevented The inhaler for use when the patient is sitting up can be used for nose inhalation if required by placing the lower border above the mouth instead of below I am indebted to Mr J H Montague of 101, New Bond street London, for the manufacture of the inhalers and for his assistance and patience in carrying out my designs

To render an ordinary adult anæsthetic by this method an average expenditure of from seven to eight gallons of gas is required a further amount of three or four gallons for each additional minute will suffice to maintain anæsthesia A patient does not inhale more by this plan when properly carried out than by any method which does not involve re-breathing of expired gas The length of time which elapses between the removal of the face-piece and the return of consciousness is proportionate in a great measure to the length of time that complete anæsthesia has been kept up As with other anæsthetics care must be taken that no mechanical obstruction to respiration such as the falling back of the tongue &c, is allowed to occur

In conclusion I append a few of the more interesting cases which have been anæsthetised in this way

1 The patient was a thin woman, aged 22 years, of fair, florid complexion She was four and a half months pregnant. She dreaded the gas previous experiences having been unpleasant She went quietly to sleep and did not stir until after the dental operation was completed There was no subsequent discomfort She had no recollection of losing consciousness

2 The patient was a woman aged 22 years She was lying down The operation which was on the hand lasted 11 minutes At first there was slight drawing up of one leg but otherwise she lay perfectly still She was unaware of having "had any gas as she had felt nothing Within two minutes of the removal of the face piece she expressed herself as feeling 'as well as ever she did in her life"

3 A big florid strong man having had gas by the closed face piece became so violent that no operation could be performed upon him After an interval of 15 minutes gas was given with an open inhaler The patient went quietly to sleep until the operation was completed when he awoke quietly After the operation (the extraction of roots with an elevator) had continued for a minute and 45 seconds gas was readministered and the operation was continued for 40 seconds longer The patient felt no pain and found the gas not unpleasant

4 In this case the patient was a woman, aged 55 years, who had a large goitre There was some dyspnœa which was always aggravated by pungent smells She took the gas well and sank quietly into a sleep which was undisturbed by a change to ether. She remained quiet for 48 minutes During the operation (laparotomy) there was no change of colour or difficulty in breathing from first to last

5 The patient an old man who was suffering from acute bronchitis and atheromatous arteries, was in bed Gas was given for two and a half minutes The patient manifested no change in appearance or breathing, he knew nothing There were no after effects The operation was the incision of an abscess

6 A girl, aged 15 years was operated upon for the removal of a growth from the plica semilunaris She was under the anæsthetic for three minutes and remained perfectly quiet There were no after effects and no sensation

7 The patient a girl, aged 19 years was the subject of sapræmia jaundice and congestion at the base of one lung The temperature was 104° F and the pulse was 150 Anæsthetisation was commenced with gas and ether and was continued with chloroform Laparotomy was performed for exploration The patient recovered well from the anæsthesia There was no vomiting or nausea

In all cases where time is mentioned reference is made only to the actual duration of the operation as taken with a stop-watch

Old Burlington street, W

CASE OF A FOREIGN BODY IN THE ALIMENTARY CANAL ULCERATING ITS WAY OUT THROUGH THE ABDOMINAL WALL

BY F PRICE JONES, M R C S ENG, L R C P LOND

For the opportunity of seeing, and for permission to report, the following remarkable case my thanks are due to Mr D Howell Thomas of Swansea who in his capacity of visiting medical officer to various public institutions had the professional care of the patient during the two periods involved

The patient was a woman, aged 33 years in whom a deficiency of intellect was to some degree compensated by an excess of cunning and to whom the common expression 'a well known character in its less desirable sense would be applicable In June and July, 1895 she was under observation for some weeks and during that time developed the habit of tearing up her clothing for no obvious reason, but careful watching resulted in the discovery that she was persistently swallowing shreds of the torn articles which on many occasions were detected in her stools Various and stringent measures were taken to prevent the practice but they were of no avail and the habit was continued up to the day on which for a time she passed out of sight

After a very brief interval she came under observation again at another place where as before she was not unknown and where the recently acquired habit of eating her clothing soon attracted attention and caused much trouble Early in January 1896 the woman began to complain of abdominal pain which was constant in character, limited in position to the epigastric and umbilical regions and not much affected by taking food Up to the middle of February she was getting up daily partaking heartily of ordinary mixed diet and, in fact did not appear to be really ill At this time emaciation commenced, the pain increased in severity, and tenderness on pressure became a prominent symptom, no definite swelling could be made out but resistance to palpation was marked The patient was now kept in bed and given a lighter diet which she took well. The temperature began to rise, running up to about 102° F in the evening A week later a well defined tumour of about the size of an orange could be felt situated just above the umbilicus and not deeply placed, before long there was obvious swelling fluctuation could be obtained and no doubt now remained that an abscess had formed and was making its way to the surface, hot fomentations were applied and as the abscess became more superficial it tended to expand downwards below the level of the umbilicus When I first saw the patient she had been in bed for a fortnight Upon our arrival one morning the nurse reported that the abscess had burst during the previous night with the escape of two or three ounces of foul smelling pus The dressings being removed it was found that pus was exuding from a very narrow orifice situated one and a half inches below the level of the umbilicus and three quarters of an inch to the right of the mid line Mr Thomas having enlarged the opening by means of a dressing forceps a coloured object could be seen lying in the pus within the cavity, this was secured and withdrawn—a proceeding which had a singular resemblance to a clever conjuring trick, for the foreign body proved to be a strip of coarse blue cotton material measuring nine and a half inches in length by from two to three inches in width identified by the nurse as part of a day gown usually worn by the patient, along with it were some small shreds of red and grey woollen stuff corresponding to the material of two other garments, but this identification did not enable us to determine how long a period had elapsed since the articles had been swallowed because the corresponding garments had been torn on several occasions The abscess cavity was of about the size of a hen's egg and the sinus appeared to lead from its lowest quadrant—the most dependent part so long as the patient was up and about—and this was confirmed by the careful use of a probe

From this time the patient improved very rapidly the only treatment employed being syringing out with carbolic lotion, the sinus however persisted for a long time, it was not quite closed at the end of the year but two months later it was found to be soundly healed and the patient none the worse for her indigestible diet which since been resumed As recently as

1898, a small, clearly-defined, and sharply-depressed scar marked the site of the sinus. As to the treatment adopted it should be said that the general condition of the woman was at no time such as to give cause for alarm nor was the pain extremely severe, and so the surgical rule for promptly evacuating an abscess in the abdominal wall was ignored in favour of tentative treatment, the wisdom of this being finally vindicated by the result. All through the illness vomiting only occurred once or twice and the formation of the abscess was not accompanied by rigors; the absence of both of these symptoms in cases of "perigastric abscess" (which cases, it appears, have almost invariably a fatal ending) is remarked upon under that heading in Quain's Dictionary of Medicine. There was never any symptom of threatened intestinal obstruction. The sinus appeared throughout to be an ordinary sinus—that is to say, there was no evidence of its being a gastric or intestinal fistula. I have mentioned the small size of the external opening when first seen; an ordinary lead pencil would have been a close fit and so the possibility of the patient having inserted the fabric after the abscess had burst was quite negatived.

And now the question arises, From which part of the alimentary tract did the foreign body ulcerate its way? Without going into the anatomical and pathological *pros* and *cons* I do not think there can be much doubt that it was from the stomach.

Dobcross, Saddleworth.

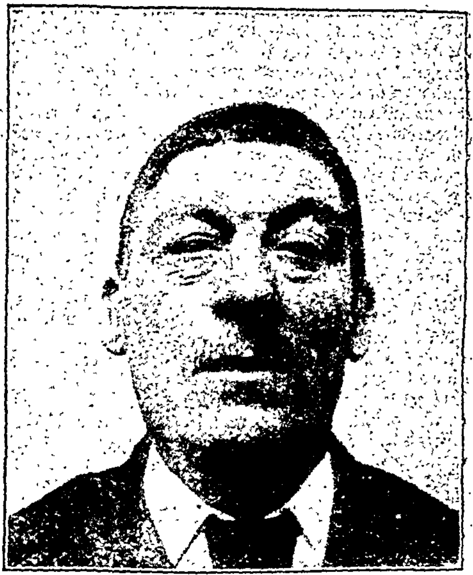
NOTE ON THE OPERATIVE TREATMENT OF ECTROPION.

BY H. CARTER MACTIER, B.A., M.B., B.CH. DUB.

THE causes of non-cicatricial ectropion are sufficiently well known, as also are the methods of treating this deformity by operation—viz., Snellen's suture, tarsorrhaphy, and Kühnt's operation—and they need not be discussed here. I shall therefore proceed to describe the details of what I believe to be a new method of operation.

In September, 1897, while I was doing duty for the visiting surgeon to the Wolverhampton Eye Infirmary a man was placed in my charge who was suffering from a senile ectropion of the left side, the palpebral conjunctiva overhanging the skin for about two millimetres. This condition had arisen in the previous April. He had been operated upon for the relief of the deformity on August 14th, Snellen's suture being the method employed, but on the removal of the suture the lid reverted to its former faulty position and it was therefore necessary to adopt some other procedure. On Sept. 10th the patient was anæsthetised with ether and I performed the following operation. A Jäger's bone plate lid-holder being placed in the left conjunctival sac and being held in position by an assistant I made a cur d incision with the concavity upwards parallel to and a two centimetres below the free border of the lid, incision being about three centimetres in length. I t carefully dissected in an upward direction through t tissues, keeping posterior to the tarsal cartilage, until the conjunctival sac was exposed and freed from attachments except at its junction with the edge of the skin at the margin of the lid. The lid-holder greatly facilitated this part of the procedure. All hæmorrhage being stopped with pressure a fine silk suture was passed after the method of Snellen, the free ends being brought out just below the lower margin of the skin wound, then a double-pointed horsehair suture was passed from the bottom of the conjunctival sac and the free ends were brought out below those of the silk suture. Both sutures were then drawn tight and tied, the tension exerted being just sufficient to produce a slight amount of entropion and the hair suture holding the bottom of the freed conjunctival sac at the level of the wound in the skin, the last wound being then sutured with a few points of horsehair. Iodoform powder was dusted on and a Gamgee pad smeared with iodoform ointment (15 grains of iodoform to one ounce of vaseline) placed over both the eye and the skin wound, the whole being secured with a roller bandage. The wound healed by first intention and I removed the sutures on the fifth day, the result being excellent, as the accompanying figure, copied from a photograph which was taken a month after the operation, shows. I must express my regret at not having had the case photographed also when the deformity existed, since a comparison of its condition before and after the operation would have had still more interest for the reader.

The failure of Snellen's method in this case was, I believe, largely due to the fact that when that method was devised suppuration was the rule and asepsis the exception, therefore the suture, by causing a septic tract, produced cicatricial bands which contracted on healing and thus cured the condition, but now when suppuration is almost a thing of the past the lid simply reverts to its faulty position when the suture is withdrawn. In the operation which I have described above the conjunctival sac and therefore the palpebral conjunctiva are pulled downwards and by healing in at a lower level draw the edge of the lid upwards and inwards thus producing a cure. The advantages I claim for this method are (1) that it is applicable to cases where Snellen's method fails, (2) that the scar left by the incision in the skin being in a natural fold is not so apparent as that of Kühnt which is vertical, and (3) that the tarsal cartilage does not require to be cut and the difficulty of bringing the two sides of a V-shaped incision together—a seemingly simple but practically very difficult matter—when doing Kühnt's operation is therefore avoided.



Wolverhampton.

Clinical Notes:

L GICAL, OBSTETRICAL, AND RAPEUTICAL.

NOTE ALYSIS FOLLOWING HERPES CIALIS.

B TER, M.B., C.M. EDIN.

JUDGING from the literature on the subject danger from eye complications in cases of herpes zoster ophthalmicus involving the supra-orbital branch only of the first division of the fifth nerve would appear to be too infrequent to call for serious apprehensions. This statement would, perhaps, not apply in those examples of herpes in which the eruption occurs on the cutaneous area supplied by the nasal branch. Induced by these considerations I wish to place on record the details of a case now under my care in which ocular paralysis has become the most prominent and (to the patient) most troublesome, if not, in view of other possible contingencies, the most serious symptom.

On Jan. 3rd, 1898, I was asked to attend a man, aged 30 years, for a supposed attack of erysipelas commencing over the right eyebrow. The history given of the case up to the time of my first seeing the patient was that common to most cases of herpes—viz., the primary patch of erythema follow[illegible]he vesicular stage, the entire patch being limited to th[illegible]of the forehead and the nasal border of it defini[illegible]urately the mesial line. Neuralgia in this insta[illegible]gan on the day preceding the first appearance of the eruption. A special feature about the arrangement of the vesicles which I think worthy of note was the tendency to confluence, and in consequence of this there was presented an uncommonly well-marked resemblance to that of pemphigus. The contents of the bullæ were at an early stage dark from admixture with blood. The neuralgic pains ceased on the third day, at which time there was nothing to indicate impending ocular trouble beyond the appearance of superficial congestion of the eyeball. There were brawny swelling and redness of the eyelids so that they could not be separated by any ordinary effort made by the patient. The eye, however, was carefully exposed each day and examined for evidence of iritis or impairment of vision from other causes, but these daily inspections revealed negative results until the tenth day, when upon examination the following condition was observed. The pupil was dilated and fixed, and was little affected by the use of eserine. The accommodation was paralysed, with micropsia, and there was crossed diplopia and divergent strabismus. The evidence supplied by the use of a lighted candle showed the superior internal and inferior recti to be affected and the inferior oblique less markedly so. The amount of ptosis which might exist from the now apparent implication of the third nerve was difficult to estimate from the difficulty of eliminating other obvious causes. A satisfactory ophthalmoscopic examination was also not easily made owing to the obstacle presented by the previously mentioned condition of the eyelids. Distant vision, however, was good. The prospect of the ultimate and complete recovery of the functions of the external ocular muscles which are affected, and the disappearance of the iridoplegia, &c. I think to be favourable, as these symptoms arise from a cause which is apparently peripheral and temporary.

The treatment adopted up to the present time has been that applicable to herpes, with a regular instillation of sulphate of eserine and rest to the eye. Massage and electricity with strychnine administered hypodermically will, I hope, form an appropriate treatment later. The employment of mechanical means to overcome the ptosis would form a necessary preliminary to the use of prisms, or a convex lens for near vision.

Ryhope, Durham

A SUGGESTED MODIFICATION IN THE TECHNIQUE OF THE OPERATION OF PAN-HYSTERECTOMY.

By O. E. PURSLOW, M.D., M.R.C.P. LOND.,
HONORARY OBSTETRIC OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM.

THE operation of pan-hysterectomy or complete removal of the uterus, including the cervix, by combined abdominal and vaginal incision is coming into gradually increasing favour, and in my opinion is the best operation for most cases of uterine fibroids in which surgical treatment is indicated. The best description of this operation with which I am acquainted is one by Christopher Martin of Birmingham in the *Edinburgh Medical Journal* for March, 1896, and this description with its accompanying diagrams has been adopted in the text-books of both Lewers and Macnaughton-Jones. The identification and incision of the vaginal wall when reached from above by stripping off the bladder from the front of the uterus constitutes one of the main difficulties of the operation. Various directions are given by different authors for doing this. Thus Martin in the article above mentioned recommends that a strong Spencer Wells forceps should be pressed up against the vaginal fornix by an assistant, the operator cutting on to the point of the forceps with scissors. Webster advises that a sound should be passed up in the same manner and pressed against the fornix and Penrose, the author of an American text-book, says, "The position of the anterior vaginal fornix may be determined by palpation and percussion, a drum-like sound is obtained by snapping the finger upon the tense vaginal wall." I venture to point out a much simpler method than any of the above. The woman being placed in the lithotomy position the vaginal mucous membrane is incised all around the cervix and the separation of the cervix is carried up as far as may be convenient; in many cases, however, it will be found that the cervix is so lifted up by the tumour as to be almost out of reach, and little can be done beyond incising the vaginal wall. This step has been advocated and practised by several surgeons, but the additional modification which I would suggest and which I believe has not been brought forward before is that the vulsellum forceps which has been fixed in the anterior lip of the cervix should be left there until it has been reached by the finger from above in the second stage of the operation. I have adopted this simple manœuvre recently and have found that it gave very great assistance in a difficult part of the operation.

REMOVAL OF A FOREIGN BODY FROM THE FOOT WITH THE AID OF THE FLUORESCENT SCREEN AND ROENTGEN RAYS.

By E. W. DIVER, M.D. DURH., M.R.C.S. ENG., L.R.C.P. LOND.

THE case here recorded may be of interest as an illustration of the difficulty often experienced in finding a foreign body, even though a skiagram may clearly indicate its relation to surrounding structures, and of the comparative ease with which removal may be effected with the aid of the fluorescent screen.

A woman, 60 years of age, consulted me in August, 1897, stating that 10 years previously she had stepped on a needle which had broken, leaving a portion embedded in her left foot, and that ever since then she had suffered from pain varying in intensity, but at all times sufficient to make walking very difficult and occasionally impossible. A skiagram was taken and the fragment was clearly displayed lying apparently between the third and fourth metatarsal bones. On August 31st the patient was placed under ether in expectation that the foreign body would be easily found and removed, but though a diligent and somewhat prolonged search was made the operation was unsuccessful. On Dec. 11th Messrs. Brady and Martin of Newcastle-on-Tyne kindly sent the Roentgen ray apparatus to the patient's house and a second operation was performed. Before the administration of the anæsthetic the foot was carefully examined with the aid of the fluorescent screen, the rays being transmitted in various directions through it. In this way it was ascertained that the needle was lying parallel with, and between, the third and fourth metatarsal bones. Ether was then administered and an incision was made in the sole, but again the needle could not be found. An antiseptic pad was then placed over the wound and a small incision was made in the dorsal surface of the foot. The screen was placed against the sole and the vacuum tube about 12 inches from the dorsum; the current was then switched on and a small hook was inserted into the dorsal wound, the shadow of the hook and that of the needle being sharply outlined on the screen. By a little careful manipulation the hook was passed around the needle and the tube and screen were removed. Daylight being then admitted to the depth of the plantar wound, the needle was easily extracted. The wounds were healed on the eighth day and the patient made a good recovery.

Although a written description may make the proceeding we adopted appear to be awkward, in practice it was exceedingly simple. This method may be of value to those who have not at hand Mr. Mackenzie Davidson's very ingenious and elaborate apparatus for localising foreign bodies. My thanks are due to Dr. Horace Paige of Gosforth who kindly administered the anæsthetic on each occasion, and also to Dr. W. Martin, of the firm of Messrs. Brady and Martin, who has given much time and attention to the practical application of the Roentgen rays and to whose skilful manipulation of the apparatus the successful issue of the operation was largely due. So clearly was the shadow of the needle depicted upon the screen that Dr. Martin expressed the opinion, contrary to the emphatically expressed statement of the patient herself, that we had to deal with the eye end and, further, that the eye itself was broken. Examination of the needle after its removal proved the correctness of Dr. Martin's view. It was a [illegible] and was one inch in length.

MIDDLESEX HOSPITAL.

A CASE OF RAPIDLY GROWING OVARIAN TUMOUR COMPLICATING PREGNANCY; OVARIOTOMY; RECOVERY.

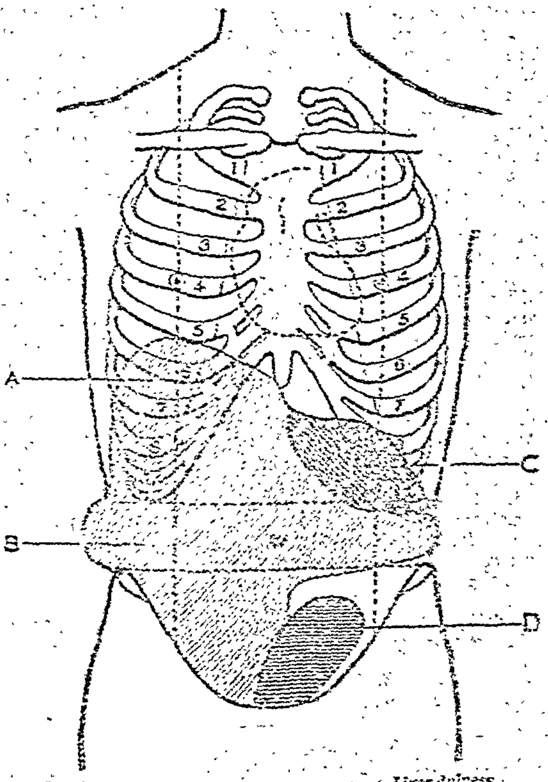
(Under the care of Dr. WILLIAM DUNCAN.)

IT would be difficult to find a case which exhibits more clearly than the one recorded below the diagnosis and the treatment of that most important complication of pregnancy, an ovarian cyst. It is not very long since many gynæcologists hesitated to attempt the removal of a cyst of the ovary when occurring during pregnancy from a fear that abortion was likely to occur. It is now recognised that on the whole there is much less danger from an ovariotomy during pregnancy than from the presence of an ovarian cyst during labour and that with ordinary care the risk of an abortion is extremely slight. For the notes of the case we are indebted to Dr. J. T. Wills, obstetric house physician.

A married woman, aged 21 years, was admitted into the Prudhoe Ward of the Middlesex Hospital on Nov. 29th, 1898, complaining of swelling in the abdomen. She was sent to Dr. Duncan by Mr. S. Peake of Shepherd's Bush. She was a pale, dark-haired woman. She had had two children; the last was born fifteen months ago. She had never been laid up apart from the confinements. Menstruation began at the age of 15 years and was regular every four weeks, and had lasted six days, two or three diapers being used daily. There was never any pain or headache. She had sometimes passed clots and shreds. She had no intermenstrual leucorrhœa. After the amenorrhœa consequent on her last pregnancy and lactation she had periods during seven months and the last period (from July 30th to August 5th) was normal in character. In June, 1898, the patient's friends told her that for some weeks they had observed that she was getting stouter, but she did not notice anything herself until September when she missed a "period." Since then she had been getting larger very rapidly, but she was unable to say where the swelling first appeared. Since September she had been unable to continue her laundry work, but had attended to her household duties. In October she had frequent but painless micturition. On Nov. 24th she had retention of urine and a catheter had to be used.

On admission the abdomen was much distended, being very prominent anteriorly and also somewhat prominent in the flanks, more especially on the right side. In the middle line there was a line of pigmentation running from the symphysis pubis to midway between the umbilicus and the ensiform cartilage. On palpation the abdomen was found to be occupied by a large swelling (with ill-defined edge in most parts) which reached (as shown in the accompanying illustration) from the costal margin to two fingers' breadth below the umbilicus on the left side, while on the right side it extended down to the pelvis; laterally it extended from the middle line six and a quarter inches on the left side and eight and a quarter inches on the right side. The surface of the tumour was smooth and fluctuation could be made out over the part lying to the right of the middle line. In the left hypochondrium a firm mass was felt, the long axis of which was inclined downwards and outwards: no definite separation of this from the cystic portion could be made out. There was dulness over the whole of the swelling and none of the dulness was modified by change of posture. The flanks were resonant. In the left lower part of the abdomen and rising out of the pelvis could be felt a pear-shaped, firm, elastic tumour (D) reaching to within four fingers' breadth of the umbilicus; over this a well-marked uterine souffle could be detected. Above this tumour there was a transverse depression separating it from the large swelling and at this line the percussion note was sub-resonant. The liver dulness (A) began at the fifth rib in the right nipple line and from this point downwards there was no resonant interval. The measurements of the abdomen were as follows: from the umbilicus to the right and left anterior superior iliac spines, 9½ inches and 9 inches respectively; from the umbilicus to the pubes and to the ensiform cartilage, 7½ inches and 6½ inches respectively; circumference of the abdomen at the umbilicus, 37¼ inches, and 2½ inches above it 33 inches. Per vaginam the cervix uteri was found to be anteposed; the os uteri was soft and patulous, admitting the finger tip. There was some violet discolouration of the vagina. The breasts were flabby and some dilated veins could be seen coursing over them and the areolæ were large and dark.

On Dec. 9th the patient was anæsthetised and an incision three inches long was made between the umbilicus and the pubes. When the peritoneum was opened about six ounces of free fluid escaped. The gravid uterus was seen in the lower part of the abdomen, while above it was the cyst. The latter was tapped with a Spencer Wells trocar and 126 ounces of clear, greenish-yellow, somewhat tenacious fluid were withdrawn. The cyst wall was brought out through the incision and the opening into it was enlarged. A finger was then introduced into the cyst so as to break down the numerous smaller cysts in the more solid portion of the tumour; these contained thick gelatinous material. The whole tumour was next drawn out through the wound and was found to spring from the right ovary. The pedicle was transfixed and tied in the usual way with silk one and a half inches from the uterus. The left ovary and tube were found to be normal. The abdominal wound was closed in three layers: (*a*) fine continuous silk for the peritoneal edges; (*b*) interrupted silkworm gut for the sheaths of the recti; and (*c*) continuous fine silk for the skin. The wound was dressed with cyanide gauze and sal-alembroth wool and a flannel binder was firmly applied. The patient made an uneventful recovery with the exception that the skin incision was very slow in uniting.



Ovarian tumour complicating pregnancy. A, Liver dulness. B, Cystic portion of the tumour. C, Solid portion of the tumour. D, Gravid uterus.

Remarks by Dr. DUNCAN.—When an ovarian tumour commences to grow coincidently with pregnancy it usually enlarges with increased rapidity (as seen in the above case) The diagnosis of this complication is sometimes exceedingly difficult I have seen an extreme case of hydramnion diagnosed as ovarian cyst, but in hydramnion the intermittent uterine contractions can be felt, besides which some parts of the fœtus can be detected through the fluid Usually when an ovarian cystoma complicates pregnancy the two tumours are separated by a longitudinal sulcus but in this case the depression was transverse. Then, again, auscultation is very valuable, as a uterine souffle (and perhaps the fœtal heart) can be heard over the gravid uterus but not over the cystoma There is at the present day a general consensus of opinion that the proper treatment of an ovarian tumour complicating pregnancy is to perform ovariotomy Tapping a cyst is quite unjustifiable in my opinion, as one never can be certain of the nature of the cyst contents (especially of pelvic cysts), and the fact of pregnancy co existing renders ovariotomy little (if any) more dangerous to the mother Practically the only extra risk is that of causing abortion or premature labour Particularly is this the case if there be adhesions between the uterus and the ovarian tumour It has been recommended in the case of pelvic tumours to perform vaginal ovariotomy but personally I prefer in all cases to open the abdomen I have removed two dermoid pelvic tumours in patients who were in the ninth and eighth months of pregnancy respectively and in both cases I was able to push the gravid uterus to one side of the abdominal cavity whilst the tumour was got up out of the pelvis and removed When an ovarian tumour is detected for the first time after labour has set in the treatment will depend on the position of the tumour and also on the extent to which it interferes with the passage of the child. A cyst in the abdomen which is of moderate size and does not prevent the head from engaging in the pelvic brim may be left alone until after the puerperium, but when it is of large size and subject to injurious pressure it had best be removed by ovariotomy The cases however, which are most dangerous and difficult are those in which a tumour in the pelvic cavity (often dermoid in character) causes more or less obstruction to the passage of the child As a rule these are not detected until labour has set in, when this is the case the first indication is to try to push the mass out of the pelvis by means of vaginal or rectal manipulation when the patient is completely anæsthetised In the event of this proving successful the uterus should be pressed down so as to prevent the tumour falling back and delivery effected by forceps as soon as the os uteri is sufficiently dilated After the reduction of such a tumour the patient must be carefully watched during the puerperium for signs of suppuration of the tumour or twisting of its pedicle, either of these complications calls for immediate ovariotomy otherwise the operation can be deferred until the patient is convalescent after her confinement But supposing that the tumour cannot be pushed up out of the pelvis, what then is the best course to adopt? It has been recommended to puncture the tumour, draw off its fluid contents, and then deliver the child either by the forceps, version, or craniotomy, but although successful cases of this kind are recorded it is a method of treatment which in my opinion exposes the mother to too great risk whilst it at the same time usually involves sacrificing the child's life If I had to deal with a case of labour complicated by a pelvic tumour I should first attempt (under anæsthesia) to push the tumour above the pelvic brim Failing in this I should be guided in the further treatment by the surroundings of the patient and the presence or absence of skilled assistance With good assistance and surroundings I should open the abdomen, push the gravid uterus to one side (or even bring it outside) then pass my hand into the pelvis, bring up the tumour, remove it, and close the abdomen in the ordinary way, subsequently completing delivery with the forceps But if the tumour was found to be matted in the pelvis by numerous and dense adhesions I should perform Cæsarean section and having carefully sewn up the uterine incision I should proceed to remove the tumour In a case however in which the hygienic surroundings were bad and skilled help was unattainable the best course would probably be to make an incision into the tumour through the posterior vaginal wall scoop out as much as possible of its contents with the finger then pass some iodoform gauze into the cavity and deliver the child by forceps or version

ROYAL INFIRMARY, LIVERPOOL.

A CASE OF GUMMA OF THE LIVER TREATED BY OPERATION.

(Under the care of Mr RUSHTON PARKER)

THE diagnosis of gumma of the liver is often extremely difficult and the nature of the swelling may not be recognised until an incision has been made into it When this has been done there can be little doubt that removal of more or less of the contents will prove beneficial, for the amount to be acted on by the anti syphilitic treatment will be materially diminished At a meeting of the Clinical Society of London in November of last year Mr W G Spencer read an interesting paper[1] on Three Cases on Gumma of the Liver in which operation was followed by relief One of these closely resembled the case under the care of Mr Rushton Parker recorded below The fact that medical treatment will suffice to cause the absorption of a gumma need in no way deter us from removing in whole or in part these swellings if they have for any reason been incised In the skin the healing of many gummatous ulcers is often accelerated by scraping

A man aged 29 years was admitted into the Royal Infirmary, Liverpool, on June 17th, 1898 suffering from pain and a swelling in the region of the gall bladder About two years previously he had had abdominal pain vaguely described, but no swelling After medical treatment for a month he was relieved About five months before admission a convex swelling which was attended by increasing pain had appeared below the right costal margin and behind the abdominal wall The swelling was about two inches wide was continuous with the liver dulness, and moved downwards with inspiration There was no jaundice and no diagnosis was made beyond a suspicion that it might be a distended gall bladder An operative exploration was undertaken on June 27th through a slit in the right rectus muscle exposing the lump which was found to be in the liver. The convex projecting portion was cut into and proved to be only part of a very large structure which extended some four or five inches in each direction and was evidently a gumma being composed of grey friable lymphy, fibrinous material Not more than a third or a fourth part was capable of safe removal and under a stream of hot water the divided margins of the liver were stitched together, then the slit in the rectus muscle was separately sewn and finally the integuments were sutured The wound healed in 12 days without discharge and the skin sutures were then removed Three days after the operation the patient was given one sixteenth of a grain of perchloride of mercury and seven and a half grains of iodide of potassium in half an ounce of water three times a day The only rise of temperature was to 100° F. on the second day and to 99 5° on the next day

Remarks by Mr RUSHTON PARKER —Before going to the infirmary the patient had been seen a few times by Dr Pethick of Woolton who told me that he thought the swelling was either a distended gall bladder or an abscess of the liver, rather inclining to the former opinion and he had sent the patient to the infirmary with the idea of having the diagnosis cleared up Dr Pethick had prescribed sodic benzoate and salicylate without appreciable benefit No history of biliary colic had been elicited by Dr Pethick or by us nor had any of us observed any signs of biliary obstruction I had no more hesitation in removing a portion of this gumma than I had in leaving the remainder to be dealt with by anti syphilitic drugs No suspicion of syphilitic tumour having arisen it is impossible to say whether or not the drugs would have sufficed for relief, entire or partial, without operative interference The removal of tension and of a substantial part of this large mass of broken-down infiltration under antiseptic conditions was attended by a cessation of symptoms which had previously disabled the patient and healing occurred in the entire absence of adventitious wound complications It is of course not usual to excise either partially or totally gummata which in the first instance are recognised as such, though it not unfrequently happens that tumours are removed for sufficiently good reasons which afterwards or even at the time are discovered to be gummata Even after the administration of anti syphilitic drugs gummata do not invariably disappear and in critical situations such as here or in the brain it is agreed that too much valuable time should not be spent in the expectation of relief being obtained from drugs. When gummata have broken down, ulcerated through the skin, and become riddled with more or less septic sinuses they frequently heal under otherwise most unpromising conditions when once anti-syphilitic drugs are suitably administered. But it might have gone hard with the patient in the present case if that extensive gummatous area had suppurated after ulceration, perforation, and secondary infection of the interior. So it may be considered fortunate for him that the pain and other conditions led to an exploration which revealed the diagnosis in the absence of such complications. Though the extirpation was only partial it appeared at the moment of exposure to be very desirable as a help to recovery and in this it has apparently fully succeeded. The man was seen in November, 1898, when he was found to be free from all symptoms of disease and had a sound depressed scar at the seat of the operation.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Cases of Abdominal Section.—Rheumatic Tonsillitis.

A MEETING of this society was held on Jan. 27th, the President, Mr. LANGTON, being in the chair.

Mr. J. HUTCHINSON, jun., read notes of three cases in which he thought it necessary to perform Abdominal Section. In none of them was there any external wound. Case 1.—A man, aged 32 years, was run over and subsequently became collapsed. Slight abdominal distension and much tenderness were present with dulness beyond the left linea semilunaris which shifted with change of position. On the following day the temperature had risen to 102° F., and the abdominal distension had increased. On opening the abdomen he found it full of blood, but in spite of careful search he could find no vessel requiring ligature. Great relief followed the removal of the blood, but some oozing occurred subsequently, as evidenced by dulness in the flanks and the escape of blood into the dressings. He left the hospital a month later. Mr. Hutchinson raised the question whether the presence of effused blood within the peritoneal cavity was likely to prove injurious and he thought it was. Case 2.—A woman was brought to the hospital with symptoms pointing to intestinal obstruction. On opening the abdomen over two pints of clear, pale, yellow odourless fluid escaped. The intestines were slightly congested, the stomach was dilated, and the uterus was enlarged as at the third month of pregnancy. He was at a loss to discover the nature of the fluid and closed the wound. In spite of a passing improvement the patient aborted on the following day and died soon after. Post mortem the abdomen again contained a large quantity of the same serous fluid and the intestines showed signs of commencing peritonitis. Exactly in the middle line of the posterior surface of the bladder, one inch above the peritoneal reflexion, and therefore hidden from view, was a small round perforation one-seventh of an inch in diameter, through which urine could readily be expressed. The bladder and urethra were otherwise normal. If the nature of the fluid had even been suspected he thought it might have been possible to discover and repair the perforation. He surmised, under the circumstances, that the wound was caused by an unskilful attempt to procure abortion. From the history it seemed likely that urine had been leaking into the peritoneum for at least four days. He discussed the effects of effused urine in the peritoneal cavity and recalled that experiments on animals had shown that healthy urine might be injected into the abdomen without giving rise to much local reaction and that in moderate quantities it might be absorbed and the animal recover. Case 3.—A woman, aged 47 years, was admitted with the history that, previously in perfect health, while lifting a basket on the preceding day she had been seized with pain in the left side of the abdomen followed by vomiting and some collapse. A smooth, moveable tumour could be made out to the left of the middle line of about the size of a fœtal head. This was dull on percussion but there was no dulness in the flanks. Nothing of interest was made out by vaginal examination. On opening the abdomen a quantity of characteristic glairy fluid escaped and it was seen that the largest cyst of a multilocular ovarian tumour had ruptured. The fluid was sponged away but the cavity was not irrigated. Recovery followed. Admitting that the thin serous fluid of an ordinary ovarian cyst might if effused in the peritoneal cavity undergo absorption without giving rise to much trouble he asked whether this thick, glairy fluid would prove equally innocuous.—The PRESIDENT, commenting on the first case, observed that though blood in the peritoneal cavity need not give rise to septic mischief it would nevertheless be advisable to operate because one could not know the conditions which had given rise to the effusion and he related the case of a man who had received a bullet wound three inches below the nipple. As there was internal hæmorrhage he opened the abdomen and found that the liver had been extensively lacerated, but ultimately he managed to arrest the hæmorrhage and the patient recovered.—Mr. L. A. DUNN pointed out that the blood which had oozed after the operation although considerable in quantity did not seem to have done any harm. The President's case was not altogether parallel because the bullet-wound was, or might be, septic.—Mr. HUTCHINSON, jun., insisted on the great relief which had followed the operation in respect of the pain, adding that he had purposely left the lower part of the wound loose so as to allow of the escape of any subsequent effusion of blood.—Dr. BATTY SHAW, in reference to the third case, related the case of a woman who was admitted to hospital three days after labour. After delivery it was noticed that there was something abnormal in the abdomen and she was sent into the hospital with the diagnosis of rupture of an ovarian cyst. She died on reaching the ward and post mortem they found a pale straw-coloured fluid in the abdomen without any sign of inflammation and a collapsed ovarian cyst. He remarked that there had been no noteworthy increase in the quantity of urine passed since the accident. The fluid was thin, but that he suggested might be due to dilution with fluid secreted by the peritoneum.—Mr. CHARTERS SYMONDS related the case of a girl, aged 14 years, in whom he had recognised the presence of an ovarian tumour, but when she was on the operating table no trace of the tumour could be found, though there was nothing in the recent history pointing to rupture. He opened the abdomen all the same and found the peritoneal cavity full of serous fluid together with a ruptured ovarian cyst. The patient recovered. He also related the case of a woman, aged 35 years, who came in with a history pointing to rupture of an ovarian cyst. Owing to special circumstances there was a delay of some days in operating and when this was decided upon she was in a serious condition. She died from shock, and though there was much fluid in the abdomen there were no signs of inflammation. He thought that if he had not operated this patient might have recovered.—The PRESIDENT thought that the extravasation of a thick viscid fluid with the things that it might contain might not improbably determine peritonitis. He related the case of a woman with an ovarian tumour in which spontaneous rupture followed by shock and ultimate recovery took place no less than four times. After the last rupture he opened the abdomen and removed the collapsed cyst. There had never been any peritonitis or any adhesions.—Mr. HUTCHINSON, jun., in reply, asked what was the cause of death in Dr. Shaw's case, as there was no peritonitis. He mentioned a case in which a woman ruptured an ovarian cyst from being thrown forward in a cab.

Dr. BERTRAM ABRAHAMS read a paper on Rheumatic Tonsillitis. The material upon which this paper was based was mainly composed of cases of rheumatic tonsillitis observed by Dr. Abrahams during the last three years. A large number of cases of chorea, rheumatism, and cardiac disease, both in adults and children, had been investigated and tabulated and the resulting statistics compared with those of previous observers in order to ascertain as accurately as possible the relation of the affection of the throat to the rheumatism. The bacteriology of many of the cases had also been studied with a view to obtaining some light upon the etiology of the disease itself. The bulk of the work in so far as it related to children was done in the out-patient department of the Evelina Hospital for Sick Children. Dr. George Carpenter was kind enough to permit the use of the material and also to allow the results to be compared with his own works for the last ten years. Details were given in the paper of a number of cases illustrating: (1) the occurrence of endocarditis after non-scarlatinal tonsillitis without the intervention of arthritis or chorea; (2) tonsillitis immediately followed by a first attack of chorea

(3) repeated attacks of chorea each preceded by tonsillitis; and (4) the occurrence of sore-throats at various points in the rheumatic series. Clinically, five varieties of rheumatic throat affection might be distinguished. 1. Faucial erythema, the pharyngeal inflammation described by Trousseau as ushering in an attack of acute rheumatism. 2. Follicular tonsillitis. 3. Quinsy. Between these latter no pathological distinction could at present be drawn, though it was notable that when a patient had repeated attacks they were almost always solely of one kind or the other, an alternation being rarely observed. As was also the case with non-rheumatic forms, the follicular variety was commoner in children, quinsy in adults. 4. The abortive form described by Singer, in which the joint and muscle pains were vague. 5. Chronic rheumatic tonsillitis, described by Dr. Max Thorner; this affection was more probably gouty in nature. A statistical inquiry was made into consecutive cases of three distinct affections—namely, 248 of chorea, 43 of acquired heart disease in children unassociated with chorea, and 66 of rheumatic fever in adults. Of the cases of chorea in which a reliable history was obtainable 53·4 per cent. had a family or personal one of sore-throat. This was not associated with any marked predisposition to either arthritis or heart disease. Of the cardiac cases 66·7 per cent. gave a history of throat affections. Among the adults 45·5 per cent. had a definite throat history, 21·2 per cent. had suffered from ulcerated throats within three weeks of the attack of acute rheumatism, and 47·2 per cent. showed faucial erythema within two days from its onset. In children, where the commencement was insidious, faucial erythema was extremely rare. On the other hand, a large proportion of them had follicular tonsillitis when first seen, several being brought up on this account and either revealing cardiac disease when examined or developing chorea while under observation. There seemed little reason to doubt that in many of these cases the tonsils might have been the channel of infection. Bacteriological examination of the tonsils and their exudation in a large number of cases revealed the constant presence of streptococci and staphylococci, the former more frequently, but the latter oftener in pure culture. Similar organisms were found in the urine drawn from the bladder with all antiseptic precautions. Taking these results together with the discovery of the same microbes in the blood and affected joints in acute rheumatism by Sahli and others, the probability of the occurrence of infection through the tonsil became very strong. It was believed by many that the rheumatic patient was poisoned by the attenuated virus of a germ which when fully active leads to pyæmia. The following conclusions were put forward: 1. The more common varieties of rheumatic sore-throat fell into two main categories—faucial erythema and tonsillitis proper. 2. Faucial erythema was most common in adults, and rheumatic tonsillitis in children, in whom it usually assumed the follicular type, quinsy being more frequent in older subjects. 3. Faucial erythema was an initial manifestation of acute rheumatism and tonsillitis might be the actual primary lesion. 4. Many cases were now definitely on record in which endocarditis had followed a non-scarlatinal tonsillitis unaccompanied by joint pain. In numerous other instances the tonsillitis had immediately preceded an attack of arthritis or of chorea. 5. The presence of the same micro-organisms in the tonsils, joints, blood, and urine was evidence in favour of the participation of pyogenic cocci in the etiology of rheumatism.—Dr. **KINGSTON FOWLER** was glad to have Dr. Abrahams' confirmation of his own observations first published in 1880. He agreed that tonsillitis might be followed by rheumatism or chorea or endocarditis. He questioned the accuracy of the term "ulcerated sore-throat" since in ordinary tonsillitis no ulceration properly so-called was present. He recalled the case of a man who was admitted into hospital with quinsy for which he was being treated with chlorate of potash and iron. He remarked at the time that if he had seen this patient on his admission he would have felt disposed to give him anti-rheumatic remedies. Eight days after this while still in bed this patient had an attack of acute rheumatism. He urged that if the rheumatic nature of these throats were recognised in good time and anti-rheumatic remedies administered the attack of rheumatism might be averted. He also mentioned the case of a man who had a sore-throat just before going on his holidays. He went mountain-climbing, nevertheless, and was laid up in the high Alps with a severe attack of rheumatic fever. He deprecated the use of the term "growing pains," such pains being in reality rheumatic.—Dr. J. W. **CARR** asked whether the diagnosis of these supposed rheumatic throats was made from the history or from the subsequent occurrence of rheumatism. In one of Dr. Abrahams' cases the interval between the sore-throat and the rheumatism was a year and in another 17 years. He suggested that an ordinary tonsillitis might attack rheumatic as well as other subjects. He had not been able to convince himself that anti-rheumatic remedies modified the course of these cases of tonsillitis. He defended the use of the term "growing pains" which he thought were actually as described. He himself had suffered therefrom, yet he was not rheumatic.—Dr. **LUCAS BENHAM** thought that any kind of sore-throat might be followed by rheumatism, but the sore-throat always seemed to precede the rheumatism and even to be the cause of it. He related a case of a child who had ordinary tonsillitis lasting three days and just when he was getting well there was a rise of temperature and a mitral murmur developed. He pointed out that when there was great œdema of the tonsils a slough might form at the point of contact and be followed by an ulcer.—Dr. G. A. **SUTHERLAND** admitted that it was difficult to demonstrate the connexion between sore throat and rheumatism, but some still asked whether erythema nodosum and chorea were rheumatic manifestations. He suggested that the tonsils might not be the only structures attacked and referred to cases in which there were headache, vomiting, and general malaise without any localising sign in association with well-marked tonsillitis in patients who subsequently developed rheumatism. He thought that the lymphoid tissue of the alimentary tract might share in the process and called attention to the occurrence of "rheumatic appendicitis."—Dr. **TOOGOOD** said that according to his experience most cases of follicular tonsillitis were of bacterial origin and were markedly infectious. The organisms which he had met with were streptococci and staphylococci and sometimes the short diphtheria bacillus.—Dr. **ABRAHAMS**, in reply, explained that "growing pains" and "ulcerated sore-throat" were merely colloquial expressions which one had to make use of in questioning patients. He was not satisfied that the anti-rheumatic treatment of these throats had any beneficial effect and he mentioned a case to show that the administration of the salicylates could not be relied upon to avert the subsequent occurrence of an attack of rheumatism. The non-success of anti-rheumatic treatment, he thought, was in favour of a bacterial origin. He concurred with Dr. Sutherland's remarks as to the gastro-intestinal disturbance in some of these cases. He pointed out that the germs referred to by Dr. Toogood were not invariably present and possibly an attenuated form was the true cause of rheumatism.

OPHTHALMOLOGICAL SOCIETY.

Rapid Changes in Refraction in connexion with Diabetes.—The Stereoscopic Examination of Skiagraphs of Foreign Bodies in the Eye and Orbit.—Exhibition of Specimens and Cases.

AN ordinary meeting of this society was held on Jan. 26th, Mr. H. R. **SWANZY**, President, being in the chair.

Mr. H. **GRIMSDALE** read a paper on Rapid Changes in Refraction in connexion with Diabetes. A female, aged about 45 years, was first seen on Oct. 7th, 1897. She had been always thin and delicate and had been losing flesh. She had been wearing for near vision—right, spherical + 1 D., cylinder + 0·75 D.; left, spherical + 1·75 D. She had suddenly noticed a change in the power of her sight a few days before her visit; distant objects became dim and near objects became clearer. When seen the vision of the eyes was $\frac{6}{60}$; with − 2 D. spherical and − 0·5 D. cylindrical for the right eye and − 2 D. spherical for the left eye the vision equalled $\frac{6}{6}$. The result was confirmed by the shadow test. In the right lens there were several opacities near the centre; the left lens was clear, but the nucleus in each was marked. No other defect in the eyes was found. The condition was regarded as early sclerosis of the lens and glasses for distance were ordered. Dr. Stokes had shortly before discovered a large amount of sugar in her urine (26 grains to the ounce). The urine had been frequently examined in previous years and had contained no sugar. After 10 days the vision had returned to its former condition, that of the right eye being $\frac{6}{18}$, with − 0·5 D. $\frac{6}{9}$, and of the left eye $\frac{6}{6}$. The right lens showed irregular astigmatism, but the opacities were unaltered. About three weeks later the patient died from diabetic coma. The interest of the case lay in the development of myopia and its rapid disappearance. A similar case was reported by Risley[1] in which disappearance of sugar in diabetes was accompanied by development of hypermetropia followed by a return to normal when the sugar reappeared. The cause is probably a lenticular one; it was impossible to assume an alteration in position of the retina; it was not likely to be due to spasm of the ciliary muscle as this would have involved a permanent spasm in Risley's case suddenly giving way and then reappearing.

Mr. **DOYNE** quoted the case of a diabetic man, aged 43 years, whose vision and refraction were hypermetropic 3 D. $\frac{6}{6}$. After a voyage vision was $\frac{6}{18}$ + 2 D. $\frac{6}{6}$. The sugar then disappeared under treatment and vision was emmetropic or hypermetropic 0·5.

Mr. **MACKENZIE DAVIDSON** gave a demonstration of the most recent changes and developments he had made in his method of investigating the presence and position of foreign bodies in the orbit and eyeball. Two negatives were taken, the light being changed in position about six centimetres, the interocular distance. If these were examined side by side against a window with a little practice in converging the eyes a miniature stereoscopic picture started into vivid relief and a fairly accurate estimate could be made of the situation of the foreign body in relation to a known point such as a piece of lead wire attached to the lower eyelid. The best instrument for seeing stereoscopic skiagraphs was Wheatstone's reflecting stereoscope. If the stereographs were reversed the object still stood out in perfect relief, but it appeared to be in the other eye; this would not give rise to any confusion as it would always be known in which eye the foreign body was lying. Mr. Mackenzie Davidson had applied his method of localising foreign bodies in the eye in 70 cases and he claimed for it an indispensable position in ophthalmic practice.

Mr. **SILCOCK** spoke of a case in which a foreign body had passed through the cornea and lens and was located by Mr. Mackenzie Davidson about six millimetres from the optic disc. Under an anæsthetic an incision was made through the sclerotic and the magnet introduced close to the foreign body which was withdrawn.

Mr. **ADAMS FROST**, Mr. **JOHNSON**, Mr. **TAYLOR**, and Mr. **CARGILL** spoke of cases under their care.

The following card specimens were exhibited:—

Dr. **J. HERN**: Obstinate Conjunctivitis.

Mr. **D. C. LLOYD OWEN**: The Cartella Eye Shield.

Mr. **W. H. JESSOP**: Skiagraph of a Foreign Body in the Eye.

Mr. **JOHN GRIFFITH**: Microscopical Specimen of Primary Sarcoma of the Cornea.

Major **M. T. YARR**, R.A.M.C.: Patch of Central Choroido-retinitis simulating in appearance the Optic Disc.

Mr. **C. HIGGENS**: Case of Removal of the Lens for High Myopia.

Dr. **E. C. FISCHER**: Associated Movement of the Lid and Jaw.

Dr. **A. BRONNER**: (1) Congenital Tumour of the Cornea; degenerated nævoid growth?; and (2) Tuberculous Tumour of the Iris.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Specimen.—Resolution on the Vaccination Act.—Exhibition of Radiographs.—Removal of Tumours.—Some Points in the Surgery of the Paralyses of Children.

A MEETING of this society was held on Jan. 26th, Dr. R. S. **ARCHER**, Vice-President, being in the chair.

Mr. **ANDREW STEWART** showed a Leg amputated for Sarcoma behind the Knee.

Dr. **PERMEWAN** moved:—

> That the members of the Liverpool Medical Institution are of opinion that the Vaccination Act, 1898, was enacted in direct opposition to the findings of the Royal Commission; that the operation of the Act will be prejudicial to the public safety and that its amendment is urgently required.

In introducing the motion Dr. Permewan said that he thought it the duty of every association of medical men to express themselves unmistakeably on the pernicious character of this Act. The principle of contracting out ought not to be applied to sanitary legislation; either vaccination should be absolutely voluntary or compulsion should be complete and efficient. It was most illogical to prosecute and convict of manslaughter parents who omitted to provide medical attendance for their children during illness because they conscientiously believed such attendance to be useless, and at the same time allow them on what were called conscientious grounds to neglect to provide for their children what the Royal Commission had found to be a protection against a specific loathsome disease. The results of the Act had been most lamentable.—The resolution was carried *nem. con.*

Mr. **C. THURSTAN HOLLAND** showed Radiographs of the Normal Chest of a boy and also of the Chest of a boy in whom the left apex was in a state of tuberculous consolidation. The difference was most marked, as also was the difference between the two sides in the affected child; this difference could also be plainly seen with the fluorescent screen. The exposure with a coil giving a 10 in. spark was 60 seconds; the boy was six and a half years of age.

Mr. **BANKS** described three cases of Removal of Tumours lying External to and Behind the Tonsil. The first case was that of a young man in whom the tumour had been growing for many years. It was removed by the mouth, a vertical incision being made over it, and was easily shelled out without hæmorrhage; it was found to be an adeno-fibroma, as had been diagnosed. The second was a precisely similar case in a woman, aged 40 years, with a history of two years' growth of the tumour. As she was very stout and full-blooded a preliminary laryngotomy was done and the pharynx was packed with sponge, but the bleeding was only trifling, and the tumour was easily shelled out with the finger. In the third case the patient was a woman about 20 years of age. A preliminary laryngotomy was done and the pharynx was plugged, then a free incision was made over the tumour and enucleation effected. The tumour was found to be adherent to bone and proved to be sarcomatous.

Dr. **PERMEWAN** described two cases of Tumours of the Œsophagus which he had removed by sub-hyoid pharyngotomy. The first patient, in whom the growth was benign, died from the immediate effects of the operation; the second recovered.—Mr. **NEWBOLT**, Mr. **BANKS**, and Mr. **LARKIN** spoke.

Mr. **ROBERT JONES**, in a paper on Some Points in the Surgery of the Paralyses of Children, deplored the lack of interest displayed by the profession in the treatment of these affections. Their pathology required working up and further experiments ought to be made. These should consist of inoculations at an early stage and of a search for the microbe. In view of recent experiments of his own, of outbreaks of an epidemic character at Stockholm, in America, and in Australia, there was strong evidence of the influence of infection. With care most of the deformities from poliomyelitis might be avoided, more especially those due to contractures. Mr. Jones discussed the question of tendon grafting and the conditions suitable to it. He thought the operation likely to prove very valuable in a number of cases. He had operated upon seven cases. In two he had inserted the sartorius into the tendon of the paralysed quadriceps. In two cases he had inserted the peronei into the paralysed tendo Achillis for talipes calcaneus. In one case he reinforced the tibialis anticus by means of the peroneus longus. Mr. Jones had operated upon over 60 cases of flail joints in accordance with the rules which he laid down in 1894. Suppuration only occurred in one case.—Mr. **MURRAY**, Dr. **WARRINGTON**, and Dr. **BARR** took part in the discussion of the paper.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 20th, Dr. Franklin Parsons, President, being in the chair.—Dr. Bruce Low read a paper on Epidemic Cerebro-spinal Meningitis, a disease in which, from its supposed infrequency in this country, little interest had been taken, and excepting the paper by Mr. B. Corney on an outbreak in Fiji 10 years ago it had been ignored by the society since 1865–67, when Professor Hirsch of Berlin and Professor Mapother of Dublin brought it before their notice. Four forms were generally recognised—the typical, the purpurous, the fulminant, and the abortive or chronic; the diagnosis of the last two was by no means easy, the definitions given in books applied to the first only, and many cases were mistaken for tuberculosis, typhoid fever, tetanus, influenza, sunstroke, and other diseases. Though its specific character was not recognised until the beginning of the present century he believed that it was not new to this country and that it had been the cause of much of the mortality previously ascribed to gaol fever and "malignant *fever with purples*." Few diseases, indeed, had been so variously designated, but at present the name of "cerebro-spinal fever" was the most approved, though the American and German vernaculars of "stiffneck fever" and "Genicksbarre" were very expressive. Cerebro-spinal meningitis, however, was a not infrequent complication of many febrile diseases and of those of the cranial bones and middle ear; this form was etiologically wholly different and never epidemic or communicable, or attended by purpura or the herpetic eruptions characteristic of cerebro-spinal fever, which was also marked by the absence of any associated disease. The epidemic fever had appeared from time to time in France, Switzerland, and America during the first half of this century, spreading later to Denmark, Italy (where in 1894 it caused 2000 deaths in a population of 30 millions), and since 1860 to Germany and the East and South-east of Europe. In 1865 there was a severe epidemic in Polish Prussia, 1900 persons being attacked and 1000 dying in the province of Dantzic alone. In the United States of America it was even more prevalent, especially in New York and other great cities, where in 1881 the deaths were equal to 0·34 per 1000 of the population. Having followed his history of the chief epidemics in Europe and America by a more detailed account of the various outbreaks in the British Islands down to the past year, he said that many deaths ascribed to influenza and other causes were probably due to this disease, and the occasional alleged instances of recovery from tuberculous meningitis, as well as the similarity in the curves of the yearly mortality from the several diseases in question, were suggestive of such confusion of diagnosis. Overcrowding, to which might be referred its greater incidence in barracks, asylums, &c., and cold and wet, whether directly or as leading to neglect of ventilation, seemed to be predisposing causes, but its infectivity was now generally admitted. Gaucher, Ughetti, Marchiafava, Celli, and Leichtenstern had between 1881 and 1886 observed micrococci in the cerebro spinal fluid of epidemic and other forms of meningitis, but they were all supposed to be identical with the pneumococcus of Fraenkel. Though Weichselbaum had in 1887 described a peculiar form of micrococcus, to which he gave the name of "diplococcus intracellularis," in six cases of the epidemic disease, it was not until 1895 that Jaeger of Stuttgart proved that this which he called "tetracoccus" was itself characteristic and causative of the epidemic cerebro-spinal fever, distinguishing it from the other forms of meningitis. His conclusions had since been fully confirmed by numerous observers in Germany, Austria, and America, and by Dr. Still in this country, who had by its means identified the so-called "infantile paralysis" with the disease under consideration. The tetracoccus was so constantly present in the nasal mucus of persons suffering from cerebro-spinal fever that Jaeger, Henbner, and others believed that the infection was always communicated through the nasal discharges, the profuseness of which in some epidemics, as that in Styria in 1898, had led to its being taken for influenza. Animals, too, were susceptible to cerebro-spinal fever, the epidemics of "influenza" among horses being doubtless due to this disease, as that in New York when 1412 died in the six weeks ending Dec. 2nd, 1872, many of them as reported at the time with meningitis and purpura which were looked on as complications, though 782 persons had died during the same autumn from cerebro-spinal fever. During the Irish epidemics of 1846 and of 1866–67 many pigs died from "the purples." Uspenski in 1896 reported a case in a dog and suggested that it was one of the diseases vulgarly comprised under the designation of "distemper." How far the disease might be spread by the intervention of domestic animals and how long or under what conditions the tetracoccus could maintain an extracorporeal existence were problems which with our recently acquired knowledge of the specific microbe distinguishing it from non-specific or pneumococcal meningitis we should ere long be in a position to decide.—Professor Notter said that the cases he had seen in India were exclusively among the men in crowded barracks, the officers, non commissioned officers, and married men having been exempt.—Mr. H. Stoit stated that in America the herpetic eruption was looked on as diagnostic of the specific disease.—Dr. Washbourn disapproved of the term "epidemic" since the specific disease was frequently sporadic especially among children. Influenza rendered the individual specially susceptible to pneumococcal infection which might set up a meningitis, but the nature of each case could be easily determined by the examination of the fluid obtained by aspiration in the lumbar region, which would show either tetracocci or pneumococci. —Dr. Still had found the tetracoccus in all the cases he had examined of the post-basilar meningitis of infants which he therefore believed to be identical with sporadic specific cerebro-spinal meningitis. In these the retraction of the head was very constant, optic neuritis was rare, but amaurosis was frequent, and he had seen the eruption though on two occasions only; the duration of this form was also longer but the seasonal incidence was the same, viz., in autumn and spring.—Dr. Bruce Low, in reply to a question, said that lumbar puncture if performed below the end of the cord was devoid of danger, easy, and almost painless, and in our present state of knowledge really indispensable to the correct diagnosis of all but typical cases. The cases associated with rheumatism, joint affections, parotitis, otitis, &c., were pneumococcal.

---

[1] Transactions of the American Ophthalmological Society, 1897.

SOCIETY OF ANÆSTHETISTS.—An ordinary meeting of this society was held on Jan. 20th, *Dr. Dudley Buxton*, President, being in the chair.—Mr. Henry Davis, in reopening the discussion on the Choice of an Anæsthetic, said that the safety of the patient must be their first aim. He preferred to commence the administration with gas and ether, thus steadying the patient and enabling him to withstand the shock of the operation better. Subsequently he changed the anæsthetic if he deemed it desirable. In operations upon the upper air passages he employed gas and ether; when the operation was prolonged he continued with chloroform even though the patient was in the sitting posture. He regarded the position of the head as of importance and described the posture which he preferred in various operations. For abdominal operations gas and ether sufficed, but chloroform was often requisite to produce the necessary muscular relaxation. In "alcoholics," although gas and ether often answered, in some cases chloroform was required. In heart disease if serous effusions existed ether was practically contra-indicated. The same applied in diseases of the kidneys.—Mr. Warrington Haward did not agree with much of what had fallen from Mr. Owen about ether. Personally he believed that the anæsthetic when properly given was as suitable for children as for adults. Statistics certainly showed that it was the safer anæsthetic. Mr. Barker had said that the anæsthetic might be regarded from two points of view, that of the anæsthetist and that of the surgeon, but Mr. Haward thought the most important point of view was that of the patient, and he believed that this was invariably "safety." "Above all other things let it be a safe one." No adequate proof had been advanced which shook his belief that ether was in every sense the safer anæsthetic. As to its being less agreeable that was, even if true, which he doubted, a minor consideration. In abdominal surgery ether had always fulfilled his requirements, complete muscular relaxation being obtained. In operations on the throat the use of ether did not, he contended, increase hæmorrhage; although he had given ether successfully in staphylorrhaphy he admitted that chloroform was more convenient as was the case in operations on the larynx and upper air-passages. Cocaine he considered most dangerous for children. Possibly in cases of abdominal distension and intestinal obstruction with vomiting local anæsthesia by cocaine might be useful.—Sir Felix Semon contended that in chronic stenosis of the upper air-passages chloroform was the best anæsthetic, as ether increased the dyspnœa and the liability to subsequent pulmonary complications. He narrated a case in which he performed laryngectomy, the patient being anæsthetised with ether by the rectum. The patient died within 24 hours, mainly, he thought, from the severe complications set up by the ether. In operations on adenoid vegetations he contended that chloroform if skilfully given was the best anæsthetic, since it allowed the careful and not hurried performance of the operation. It was to be regretted that many persons undertook such cases without sufficient experience or manipulative skill, and this fact he submitted accounted for very many of the fatalities which had occurred when this operation was in progress.—Dr. G. H. Savage had found the insane take various kinds of anæsthetics with equal safety. Chloroform appeared to produce most after effects, causing in some instances mania, &c. As a curative agent in cases of violent mania chloroform was in Dr. Savage's opinion probably most useful. Certainly the insane, as a rule, took anæsthetics well.—Dr. Macnaughton Jones thought that in 90 per cent. of the cases requiring an anæsthetic ether was best on the grounds of its safety and celerity of action. Chloroform was unfortunately given by anybody and everybody. Every practitioner considered himself able to give it and the use of lint favoured this fatal error. He pointed out that collapse was often the result of the operation although attributed to the anæsthetic. Dangers occurring under ether were easily recognised and remedied; those following the use of chloroform were too often irremediable, but many of these were seen by the skilled and experienced anæsthetist and by his prompt action counteracted. Hence the importance of experienced anæsthetists whose knowledge enabled them to make a wise choice of the anæsthetic and to give it in the best manner. In organic lung disease and diabetes and in ophthalmic surgery he preferred ether, except in glaucoma. In gynæcological operations and abdominal surgery he preferred gas and ether. In cases of hysteria chloroform was his personal predilection. In every case, however, he felt strongly that the surgeon should after the facts of the case were placed before the anæsthetist leave him to make the selection of the anæsthetic.—Mr. Stanley Boyd was in agreement with Mr. Haward's remarks. He spoke of the dangers of chloroform in the hands of inexperienced house surgeons and believed that ether was a safe anæsthetic for children. He advocated morphia as a preliminary to anæsthesia and the lateral position for operations about the naso-pharynx and mouth. The restlessness of patients under ether during abdominal operations was often, he thought, the result of hurried anæsthesia and could be obviated with care.—Mr. Eastes preferred ether. In cases of shock, paralysis of the intercostals or diaphragm, and degeneration of the heart, in low blood tension, or cases in which the patient was sitting up, chloroform should not be given nor as a rule in cases of abdominal or pelvic surgery. For adenoid operations he gave ether but not gas, as the latter, he held, caused congestion. Diabetics took ether and chloroform well. Mr. Eastes had found the A.C.E. mixture useful and safe and he felt that the attack upon it was too severe. Cocaine he had found to be very dangerous, especially for children, causing faintness.—Mr. Carter Braine liked the A.C.E. mixture for children under six years of age; after that age he gave ether. He now gave the A.C.E. mixture in cases of abdominal distension and advocated preliminary lavage. In thyroidectomy he preferred a preliminary injection of morphia followed by chloroform.—After some remarks from Mr. Harold Low, Mrs. Dickinson Berry, Mr. Tyrrell, and the President, Mr. White replied.

NORTH OF ENGLAND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 20th, the President, Dr. Donald, being in the chair.—Dr. Nathan Raw showed a Ruptured Uterus with an Ovarian Tumour removed by abdominal section after delivery of the child. The patient, a multipara, had been in labour for three days. She was then seized with sudden pain in the abdomen and hæmorrhage, with great collapse. On examination the vaginal vault was found to be pushed down by a large swelling above resembling an ovarian cyst. The os was high up under the pubes. The umbilical cord presented and the placenta was attached to the lower uterine segment. It was rapidly separated and a foot was brought down. Intestine was then discovered in the cavity of the uterus showing that rupture had occurred. The child was rapidly extracted with forceps to the aft[illegible]ing head, and a large rupture was then detected. Sa[illegible]id was injected and the abdomen was opened. The [illegible]al cavity contained a large quantity of blood-clot and [illegible]tents of the ovarian cyst which had undergone to[illegible] ruptured. The uterus was rapidly amputated and removed together with the cyst. The patient rallied well but gradually sank and died three days after the operation.—The President made some remarks on the case.—Dr. T. Arthur Helme read the notes of a case of Degenerating Fibroid removed together with the uterus by abdominal hysterectomy. The patient, who was 29 years of age, had suffered from severe pain and hæmorrhage for eight months and on one occasion had retention of urine. The administration of ergot caused very acute pain the result of uterine contractions and had to be discontinued. As the hæmorrhage was causing uterine anæmia operation was decided upon. The uterus filled the entire pelvis. Total abdominal hysterectomy was performed, the vaginal roof being entirely covered over by peritoneum. No drainage was used. The patient made a rapid and uneventful recovery.—Remarks were made by Dr. Davies, Dr. Walter, Dr. Lloyd Roberts, and Dr. Briggs.—Dr. W. E. Fothergill read a paper on Some Auto-intoxications of Pregnancy and the Puerperium. He said that there was a large amount of evidence in favour of the conclusion that eclampsia was the result of a general auto-intoxication. The urine though small in quantity was low in toxicity, whilst the blood serum was two or three times more poisonous than the serum of health. Necrotic and hæmorrhagic lesions were constantly found in the liver in these cases and it was probable that this organ was chiefly at fault. Jaundice was frequently found associated with eclampsia and in acute yellow atrophy the liver changes were an exaggerated form of the hepatic lesions found in eclampsia. The various disorders of the nervous system, such as peripheral neuritis, poliomyelitis, &c., which occurred in pregnancy were clearly toxic in origin and it was likely also that melancholia and mania of pregnancy were also intoxications. It was probable that the extra strain thrown upon the various organs of excretion during pregnancy might lead to a loss of equilibrium between the poison production and poison excretion in the body. Although the subject was not yet fully worked out the "auto-intoxication" theory formed a good working hypothesis, and might afford a new system of classification of the various troubles of pregnancy, a large number of which might in the future be classified under the term "hepatic toxæmia" as suggested by Pinard.—Dr. Gemmell (Liverpool) said that in the puerperium many cases classed as septicæmia were unassociated with the presence of pyogenic organisms in the discharges or the blood and he considered them as toxæmic cases arising from absorption either from the kidneys, liver, or alimentary canal.—Remarks were also made by Mr. Wright and Dr. Walter.—The following office-bearers were elected for the year 1899:—President: Dr. Donald. *Vice-Presidents*: Mr. J. Benson, Dr. J. Braithwaite, Mr. J. N. Cregeen, Dr. W. E. Fothergill, Dr. J. E. Gemmell, Mr. C. Richardson, Dr. W. J. Sinclair, and Mr. G. E. K. Thorpe. Honorary General Secretaries: Dr. Arnold and Dr. W. W. Lea. Honorary Treasurer: Mr. Richard Favell. Council: Dr. R. A. Brannigan, Dr. E. Buxton, Dr. C. N. Gwynne, Mr. D. L. Hamilton, Dr. T. A. Helme, Dr. J. B. Hellier, Dr. J. D. Leigh, Dr. J. Matthews, Mr. E. H. Monks, Dr. S. Nesfield, Mr. M. Smith, Dr. D. Lloyd Roberts, Dr. J. E. Scowcroft, Dr. J. P. Stallard, Dr. J. D. Martin, Dr. D. Smart, Mr. C. Vereker, Dr. W. Walter, Dr. R. E. Williamson, and Dr. A. E. Wear. Honorary Local Secretaries: Dr. J. Scott (Manchester), Mr. W. Fingland (Liverpool), Mr. E. O. Croft (Leeds), and Dr. H. Rhodes (Sheffield).

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 18th, Dr. Cattle, Vice-President, being in the chair.—*Dr. Michie read a paper* on Suppuration in the Neighbourhood of the Pregnant Uterus and gave details of seven cases which had come under his own notice. These cases fell into three groups: (*a*) In the first was a case of perityphlitic abscess due to perforation of the appendix vermiformis by a concretion in the fifth month of pregnancy. Dr. Michie performed an operation for the removal of the appendix and drainage of the abscess cavity which extended into Douglas's pouch where the concretion was found. The patient made a good recovery. (*b*) This group consisted of four cases of pyosalpinx in each of which the appendages were removed, in one during the fifth month of gestation, the patient afterwards going on to term, delivery and convalescence being in every way normal. In another case the appendages were removed during the fourth month. The patient was, however, suffering from severe septic poisoning due to a large quantity of putrid pus in the peritoneal cavity and extensive peritonitis. Miscarriage took place 24 hours after operation and she died on the fourth day. On two others, where there was also a large quantity of sero-purulent fluid in the abdomen the operation was performed almost immediately after delivery at the fourth month and at term respectively; in both instances recovery took place. (*c*) The third group consisted of two cases of suppurating ovarian cysts complicating pregnancy which Dr. Michie had met with. In one ovariotomy was performed during the progress of labour at the sixth month.

Delivery was completed four hours after the operation and though the patient's condition was extremely critical for some days she ultimately made a complete recovery. In the last case a suppurating cyst was removed during the fifth month of pregnancy, the patient making an easy recovery and being delivered of a healthy child at term. In the light of these cases Dr. Michie drew attention to the necessity of inquiring into the previous history of patients suffering from "puerperal fever," as they showed that not in every instance was that disease due to infection conveyed from without at the time of or shortly after delivery, but that occasionally septic mischief may be in existence some time before labour takes place and be greatly aggravated and become extremely serious by the mechanical effects of that process.—The paper was discussed by Dr. Cattle, Mr. Chicken, Mr. Hogarth, and Mr. Woods.—Mr. Lander read notes of a case of Pseudo-hypertrophic Muscular Paralysis, a complete history of the patient being given from birth to death which occurred at 16½ years. Photographs were shown illustrating various stages of the disease. The latest photographs were especially interesting as they showed well-marked hypertrophy of the temporal muscles.—Dr. E. O. Kingdon showed a patient who had a small Congenital Tumour visible beneath the Conjunctiva at the lower and outer part of the left orbit and projecting prominently when the lower lid was everted. Dr. Kingdon considered it was a dermoid.—Mr. Laws suggested fatty tumour as an alternative diagnosis.—Mr. Chicken showed the following specimens: 1. Fibroid Tumour of the Uterus. Abdominal hysterectomy had been performed. 2. Tubal Abortion. 3. Hydrosalpinx.—Dr. Michie showed a specimen of Malignant Disease removed from the Transverse Colon by Enterectomy. Union was effected by suturing only. The operation had only been done four days before the meeting but complete relief of all symptoms had been secured and there was every prospect of a good recovery. The growth was an ordinary columnar carcinoma.

KIDDERMINSTER MEDICAL SOCIETY.—A meeting of this society was held on Jan. 27th, Mr. E H. Addenbrooke, President, being in the chair.—Mr. J. Lionel Stretton showed: 1. A girl, aged 20 years, upon whom he had performed Excision of the Elbow-joint three years previously. She was now able to perform the duties of a domestic servant. She could carry a bucket of water and all her movements were perfect. 2. A Cystic Tumour weighing 3 lb. 12 oz. removed from the scalp of a man, aged 69 years. Four years previously a large sebaceous tumour was removed from the same situation. 3. A man, aged 63 years, upon whom he had operated for Recurrent Epithelioma of the Lip. In order to fill up the large gap a triangular flap of skin was dissected from the neck, turned up, and fixed between the two portions of lip with a satisfactory result.—Mr. W. Hodgson Moore showed a Melanotic Sarcoma removed from the cheek of a woman, aged 69 years. The growth supervened on a mole and she refused to have it removed until it had extended so much that considerable deformity followed the operation. Mr. Moore advocated the removal of all moles as he considered them so liable to malignant changes.—Mr. Oliphant showed: 1. The Brain of a woman, aged 50 years, who died in the hospital. There was a spindle-celled sarcoma of about the size of a turkey's egg growing from the meninges over the fissure of Sylvius on the left side and compressing the frontal and temporal lobes. The points of interest about the case were: a very indefinite history and the fact that her symptoms materially improved under iodide of potassium, her pulse was never rapid, her temperature was never subnormal, there was no vomiting or convulsion, and her mental condition remained clear to within a few hours of death. 2. Skiagraph of a Fracture of the Right Tibia in a young man, aged 21 years. He slipped at football and when admitted to the hospital there was so much swelling that an accurate diagnosis could not be made. The skiagraph showed a transverse fracture through the thickest part of the lower end of the tibia and a second through the internal malleolus which was displaced downwards to an extreme degree.—Dr. B. Addenbrooke showed specimens of Tubercle Bacilli in Milk.—Mr. J. Lionel Stretton read a paper on the Treatment of Tuberculous Disease. After an interesting discussion the following resolution was adopted: "That the attention of the local authorities be drawn to the importance of safeguarding the public from the spread of tuberculous disease."

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 17th, the Vice-President, Dr. Horrocks, being in the chair.—Dr. Rabagliati showed a Fibro-myoma of the Uterus weighing 11½ lb. which had been successfully removed. The case was complicated by the presence of a malignant tumour in the left breast.—Dr. Kerr read notes on two cases of Lateral Sinus Pyæmia.—Dr. Althorp read notes on a case of Lympho-sarcoma involving the Stomach, Colon, and Rectum. The patient was an unmarried woman, aged 29 years. The first symptoms of illness were in June, 1898, and consisted of diarrhœa and vomiting with fever. The fever persisted but the other symptoms subsided with rest in bed. On Sept. 10th she was admitted to hospital with symptoms of chronic intestinal obstruction and on examination a growth of the rectum was found. It infiltrated the surrounding tissues and almost blocked the lumen of the gut, not allowing passage of the finger past the obstruction. Left inguinal colotomy was performed on Sept. 21st; the fingers were introduced into the abdominal cavity and the pelvic contents were felt to be matted together. The patient progressed satisfactorily and the bowel was opened on the fifth day. For about six weeks she was able to be up and about the ward, but at the end of that time she began to complain of abdominal pain until her death on Nov. 16th. There had been free discharge of fæces all this time. A fortnight before death a swelling was noticed in the position of the transverse colon and during the last week of life she vomited freely. At the necropsy there was found a growth involving: (1) the stomach in its pyloric half, the small curvature and spreading up to the œsophagus; (2) the cæcum, ascending and transverse colon; and (3) the rectum, matting together the pelvic contents. There was only one secondary growth which was found in the bronchial glands.—Dr. Eurich gave a description of the Microscopic Appearances of the Growth, pronouncing it to be a Lympho-sarcoma. He discussed the nature of lympho-sarcomata and suggested a parasitic origin in the case under consideration, although there was no direct evidence in the shape of organisms.—Dr. Horrocks, Dr. Goyder, Dr. Hall, and Dr. Metcalfe discussed the case.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on Jan 26th at 20, Hanover-square, W., the President, Dr. Fortescue Fox, being in the chair.—21 candidates were nominated for election.—Dr. Evelyn Crook read a paper on the Climate of Margate in Relation to Disease. He showed that the atmosphere of Margate was at all times free from the raw penetrating land fogs so prevalent in many places, and the various diseases for which a residence at Margate was particularly suitable were considered, stress being laid on the great benefit derived by patients suffering from tuberculous disease and phthisis in its early stages from a residence at Margate.—Dr. Brodie Cruickshank read a paper entitled Notes on Nairn, chiefly Climatic. Nairn, situated on the southern shore of the Moray Firth, had one of the smallest rainfalls in the United Kingdom, the average annual rainfall being 24 52 inches. The mean annual temperature for the last 10 years was 46·1° F. From June to February the prevalent winds were southerly and westerly; during March, April, May, and half June, winds from the north and east prevailed. The sea-bathing and drinking-water were good. Nairn was suitable for phthisical and tuberculous patients and had a great claim for consideration as a winter resort. Very little snow fell and mist and fog were almost unknown.—Dr. Solly, Dr. Bezly Thorne, Dr. Leon, the President, Dr. Septimus Sunderland, and Mr. MacHardy discussed the papers.—Dr. Evelyn Crook, in reply, said he believed that enlarged lymphatic glands were less liable to suppurate at Margate than in inland localities.—Dr. William Bain read a paper on the Action of certain Mineral Waters on the Biurate of Soda.—Dr. A. P. Luff said that the experiments conducted by Dr. Bain were interesting, but in his opinion it would have been better to have treated the solubility of sodium biurate in blood serum or artificial blood serum mixed with such proportions of the constituents of the waters as might reasonably be expected to be introduced into the circulation when the waters were taken.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting of this society was held at 20, Hanover-square, W., on Jan. 25th, the President, Dr. H. Radcliffe Crocker, being in the chair.—The

President read a paper on Recurrent Desquamative Scarlatiniform Erythema.—The following cases were shown:—The President: (1) A male patient with Lichen Planus; and (2) a male patient with a patch on the anterior surface of the wrist of Tinea Circinata. Fungus and mycelium from the case were shown under the microscope and also a drawing was exhibited.—The President also exhibited other interesting drawings.—Dr. Stowers: An infant with Lichen Planus and a patch of Lichen Verrucosus on the Right Index Finger.—Dr. P. S. Abraham: (1) A male, aged 50 years, with Dermatitis Herpetiformis; (2) a female, aged about 30 years, with Dermatitis Herpetiformis; and (3) Atrophodermia Guttata in a female about 30 years of age.—Dr. Russell Ryan: A case of Lichen Planus.—Dr. T. D. Savill: Two children, aged 10 and six years respectively, with (?) Psoriasis Guttata and (?) Lichen Scrofulosorum.—Dr. Savill also showed a girl, aged 19 years, with a Symmetrical Maculated-Purpuric Rash on the Thighs, Legs, and Arms.—The President, Dr. Abraham, Dr. A. Eddowes, Dr. Stowers, Dr. Savill, Mr. Pernet, and others took part in the discussions.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 25th, Mr. Alex. Miller, President, being in the chair.—Dr. Edgar showed two Ovarian Dermoids removed from a patient by abdominal section.—Dr. John Lindsay read a paper on a case of Defective Development of the Limbs. Several drawings were shown.—Dr. Robert Jardine read a paper on Saline Injections in cases of Hæmorrhage and Eclampsia. Two examples of accidental hæmorrhage and three of post-partum hæmorrhage were described. In all bleeding was very profuse and the shock was extreme. All the patients recovered. Five cases of eclampsia were described. The first patient was practically moribund when seen by Dr. Jardine, and she died, although the saline injection seemed to improve her pulse for some little time. Cases 2 and 3 were very severe examples of the disease. They both recovered. The saline injection had a most marked effect in increasing the quantity of urine excreted. Dr. Jardine considered that the saline injection should only be used in conjunction with some drug to control the fits, such as chloroform, chloral and bromide, veratrum viride, and morphia. Morphia in large doses he was inclined to think was the best. The solution used in the cases of hæmorrhage was one containing a teaspoonful of common salt to the pint of boiled water to which was added in the cases of eclampsia a teaspoonful of bicarbonate of potash.

Reviews and Notices of Books.

Dictionary of National Biography. Edited by SIDNEY LEE. Vol. LIV., Stanhope—Stovin. Pp. 446. Vol. LV., Stow—Taylor. Pp. 486. London: Smith, Elder, and Co. 1898.

THE men of letters whose names appear in these two volumes include Robert Louis Stevenson, Dean Swift, and Laurence Sterne. Stevenson was born in Edinburgh in 1850. His father, two uncles, and grandfather, all of whom were engineers in that city, are also the subjects of notice in the Dictionary. Much of Stevenson's work appeared in various periodicals, but a collected edition in twenty-seven volumes was commenced in 1894 and finished in 1898. His first popular success was "Treasure Island," published in 1883, followed in 1886 by "The Strange Case of Dr. Jekyll and Mr. Hyde" and "Kidnapped," both of which greatly increased his reputation. Stevenson was an invalid from childhood; for the sake of his health he settled in 1890 near Apia in the Samoa Islands and died there in 1894. Laurence Sterne was the son of an ensign in the army and was born in 1713. Having taken holy orders, a vocation for which he had no fitness, he held various preferments in Yorkshire and died while on a visit to London in 1768, a month after the publication of "A Sentimental Journey." Dean Swift was born in Dublin in 1667 and died in that city in 1745. The notice of him is by Mr. Leslie Stephen and extends to 24 pages.

The biographies of medical men in the two volumes are 36 in number, including 1 President of the Royal College of Surgeons of England and 2 Presidents of the Royal College of Physicians of Ireland. Edward Stanley, born in London in 1793, was apprenticed to two successive surgeons at St. Bartholomew's Hospital, was admitted a Member of the Royal College of Surgeons of England in 1814, and gained the Jacksonian Prize in 1815. He was elected assistant surgeon to St. Bartholomew's Hospital in 1816, lectured on anatomy from 1826 to 1848, and was elected full surgeon in 1838—a post which he resigned in 1861. He was elected a Fellow of the Royal Society in 1830 and was President of the Royal Medical and Chirurgical Society in 1843. At the Royal College of Surgeons of England he held in succession the most important offices. He was elected a life member of the council in 1832, Arris and Gale Professor of Human Anatomy and Physiology in 1835, Hunterian Orator in 1839, and President in 1848 and again in 1857. He was appointed Surgeon-Extraordinary to the Queen in 1858. Stanley died in 1862. His principal published works were "Illustrations of the Effects of Disease and Injury of the Bones" and "A Treatise on Diseases of the Bones." Richard Steevens was born in Ireland in 1653, studied medicine at Trinity College, Dublin, graduated there as M.D. in 1687, and thenceforward practised as a physician in Dublin, where he amassed a large fortune. He was a Fellow of the Irish College of Physicians and in 1710 was elected President of that body. He died the same year and the bulk of his property was bequeathed to found a hospital in Dublin, which hospital, since known as Steevens's Hospital, was completed in 1733 at a cost of £16,000 and was the first public hospital established in Dublin. Dean Swift was one of its earliest governors. John Sterne, or Stearne, grandson of a Bishop of Meath, was born in Ireland in 1624, fled to England on the outbreak of the Irish rebellion, and in 1643 proceeded to Cambridge, where he studied medicine at Sidney-Sussex College. Returning to Ireland in 1651 he received the degree of M.D. from Trinity College, Dublin, in 1658 and practised as a physician. In 1660 he proposed to the University that a college or hall affiliated to the University, of which he had been constituted President in 1654, should be set apart for ever as a college of physicians. The arrangement was sanctioned and Stearne, on the nomination of the Provost and Senior Fellows of Trinity College, in whom the appointment was vested, became its first President. He died in Dublin in 1669. John Sutherland, born in Edinburgh in 1808, became a Licentiate of the Royal College of Surgeons of Edinburgh in 1827 and graduated as M.D. at the University in 1831. After spending much time on the continent he practised for a short period in Liverpool where he edited "The Liverpool Health of Towns' Advocate," and in 1848 entered the public service as an inspector under the first Board of Health. In 1855, at the request of Lord Palmerston and Lord Panmure, he became the head of the commission sent to the Crimea to inquire into the sanitary condition of the English soldiers. He took an active part in the preparation of the Report of the Royal Commission on the Health of the Army, dated 1858, and also of the Report on the State of the Army in India, dated 1863. Both reports were of the greatest importance to the welfare of the soldiers and most of Sutherland's recommendations were carried out. He retired in 1888 and died at Norwood in 1891. Alexander Patrick Stewart, born in East Lothian in 1813, studied medicine at Glasgow University, graduated as M.D. in 1838, settled in Grosvenor-street, London, in 1839, and there practised till his death. In 1850 he was elected assistant physician to the Middlesex Hospital and became physician in 1855, in which year he was elected a Fellow of the Royal College of Physicians of London. He was the author of several papers on medical subjects, but his title to recollection rests upon "Some Considerations on the Nature and Pathology of Typhus and Typhoid Fever applied to the Solution of the Question of the Identity or Non-identity of the two Diseases," read before the Parisian Medical Society on April 16th and 23rd, 1840. This paper was reprinted by the New Sydenham Society in 1884. The observations on which it is based were made at the Glasgow Fever Hospital. In this essay Stewart states clearly, from his own observations, the differences between the two fevers in origin, cause, course, symptoms, and anatomical lesions. Sir William Jenner's papers in 1849, 1850, and 1853 are written on the same lines as Stewart's and are regarded as having finally settled the question. Stewart died in 1883. Thomas Hawkes Tanner was born in 1824, studied medicine at King's College, London, and graduated as M.D. at St. Andrews University in 1847. In 1851 he was elected a physician to the Hospital for Women in Soho-square. In 1858 he took an active part in the foundation of the Obstetrical Society of London. In 1860 he was appointed an assistant physician for the diseases of women and children at King's College. He was a voluminous writer, his chief work being "A Manual of the Practice of Medicine," which has passed through seven editions. He died in 1871. James Syme was born in Edinburgh in 1799 and studied medicine in that city, becoming a Member of the Royal College of Surgeons of England in 1821 and a Fellow of the Royal College of Surgeons of Edinburgh in 1823. He commenced lecturing on anatomy in Edinburgh in 1823, added a course on surgery in 1825, and in 1833 was appointed Professor of Clinical Surgery in Edinburgh University. In 1838 he was chosen surgeon in ordinary to the Queen in Scotland. He acquired great celebrity both as a teacher and a surgeon and was the author of several published works, among which may be mentioned "On the Excision of Diseased Joints" and "The Principles of Surgery." He introduced the operation for excision of the elbow into this country and devised an amputation at the ankle-joint which bears his name. He died in 1870 and was succeeded in the chair by his son-in-law, Mr. (now Lord) Lister, who had previously been Professor of Surgery in Glasgow University. William Stokes was born in Dublin in 1804. He studied medicine and graduated in 1825 in Edinburgh and was the same year elected physician to the Meath Hospital in Dublin. In 1838 he founded the Pathological Society of Dublin and in 1839 the University of Dublin conferred upon him the degree of M.D. He discharged the duties of Regius Professor of Medicine in the Dublin University from 1843 and was elected F.R.S. in 1861. He was long the undoubted head of his profession in Ireland and wrote several important works, among which are included "Diseases of the Heart and Aorta" and "Lectures on Fever." He died in 1878. Octavius Sturges was born in London in 1833, served in India as a lieutenant of artillery, returned to England in 1857, and studied medicine at St. George's Hospital and Cambridge University, graduating there as M.D. in 1867. He became assistant physician at the Westminster Hospital in 1868, physician in 1875, and lectured there successively on forensic medicine, materia medica, and medicine. He delivered the Lumleian Lectures at the Royal College of Physicians of London on Diseases of the Heart in Childhood. He died in 1895. Thomas Sutton was born in Staffordshire in 1766 or 1767. He studied medicine in London, Edinburgh, and finally in Leyden, where he graduated as M.D. in 1787. He practised at Greenwich and to him is due the discrimination of delirium tremens from the other diseases with which it had previously been confounded. He died in 1835. Sir Robert Tabor or Talbor was born in Cambridgeshire in 1642 or 1643 and was apprenticed to a Cambridge apothecary. He devoted his attention to improving the methods of administering cinchona bark in the treatment of ague, and having prescribed it with success for Charles II. he was appointed one of the King's physicians in ordinary and was knighted in 1678. He also attended the Dauphin and the Queen of Spain. He died in 1681. Alfred Swaine Taylor was born in Kent, in 1806, studied medicine at Guy's and St. Thomas's Hospitals, and took the diploma of the Apothecaries' Society in 1828. The next few years he passed mostly on the continent, but in 1831 he accepted the professorship of Medical Jurisprudence at Guy's Hospital, then first created, and he held the office till 1877. His services were for a long period in much demand as a witness in criminal investigations and his works on medical jurisprudence and on poisons are standard authorities. From 1844 to 1851 he was editor of the *London Medical Gazette* prior to its fusion with the *Medical Times*. In 1845 he was elected F.R.S. and in 1852 he received the honorary degree of M.D. from St. Andrews University. He died in 1880. Thomas Sydenham was born in Dorsetshire in 1624, served in the Parliamentary army as a captain of horse during the Civil War, on its conclusion entered Wadham College, Oxford, in 1647, and was created Bachelor of Medicine in 1648 at a very early stage of his medical studies. He began to practise as a physician in Westminster about 1655, obtained the Licence of the Royal College of Physicians of London in 1663, and took the M.D. degree at Cambridge in 1676. He died in 1689. His biographer (Dr. J. F. Payne) says of him: "His chief contributions to medicine were: first, his observations on the epidemic diseases of successive years, which have been the model of many similar researches; next, that he gave the first description or clear discrimination of certain special diseases, such as chorea, hysteria, and several others; finally, in practical medicine, he introduced the cooling method of treating the small-pox, which was new at all events in English practice, and he helped to bring in the use of bark in agues. By these discoveries and by the method of studying diseases which he introduced Sydenham is admitted to have made an epoch in medical science."

An Atlas of Bacteriology. By CHARLES SLATER, M.A., M.B. Cantab., M.R.C.S. Eng., F.C.S., Lecturer on Bacteriology, St. George's Hospital Medical School, and EDMUND J. SPITTA, L.R.C.P. Lond., M.R.C.S. Eng., F.R.A.S., formerly Demonstrator of Anatomy, St. George's Hospital Medical School. London: The Scientific Press, Limited. 1898. Price 7*s.* 6*d.* net.

WITH each succeeding year as surgery and preventive medicine progress the fundamental facts upon which they depend are brought more prominently forward, and it is owing to the importance of bacteriology in connexion with these sciences that this branch of pathology is being more and more recognised as a subject with which all medical students ought to be familiar. It is nevertheless much to be regretted that up to the present sufficient time has not been devoted to instruction in the practical part of the subject, for it is only by conscientious and painstaking practical work that a really useful knowledge of asepsis can be gained.

It is no doubt difficult to find leisure for a comparatively new study in the already over-filled days of the medical student, and it is only by omitting some portion of the accepted curriculum that a place can be found for practical bacteriology. But few thoughtful people will be inclined to dispute the statement that its study is of more real value than some of the subjects now regarded as essential.

It is with pleasure that we note a growing tendency on the part of teachers and publishers to provide earnest students with the means of [illegible] the inadequate teaching usually offered. Already several foreign books of merit have appeared, one or two of which are written especially for beginners, and there has recently been published in this country a book by Dr. Slater and Mr. Spitta of St. George's Hospital which ought to appeal to everyone desirous of becoming familiar with the appearances presented by the various bacteria usually met with and as they occur in ordinary preparations in the laboratory.

The book to which we refer is called an Atlas of Bacteriology and this exactly describes it. The volume consists of some hundred photo-micrographs taken directly from preparations made in the ordinary way in the laboratory of St. George's Hospital and it illustrates exceedingly well the more important organisms with which a student ought to be familiar. And to one point in particular we wish to draw attention. The preparations chosen although good of their kind are not of that "show" character so often noticed in published works. Not infrequently, indeed, it would appear that the desire to instruct the reader has been lost sight of in the endeavour to show what excellent work may be done. It is not so, however, in the present instance. The illustrations are from good average preparations and as such are more useful to the student than first-rate picked and special preparations could ever be. For the student has to get an idea of what an average preparation looks like, and if he is only acquainted with extraordinarily good examples he will often find himself at fault both in making original observation and also in the examination room.

Coming more particularly to the details of the book under review we consider the authors have been well advised in providing a short photographic introduction which, whilst being so short as not materially to encroach upon the other portions of the book, is yet sufficiently detailed to indicate to anyone acquainted with the subject the conditions under which the negatives were produced. As is almost inevitable where every operator has his own methods of attaining similar results there are several points upon which we are at issue with the authors, and especially is this the case with regard to focusing, which we consider can best be accomplished by an examination of the aërial image with a simple lens, without the interposition of any ground-glass screen. The employment of the condenser is another subject upon which we might be inclined to question the authors' statements, but on this point so much difference of opinion prevails and the whole matter is so ill understood by the majority of workers that it would be useless to enlarge upon it here; and, indeed, we do not wish to cavil at instructions which would enable an operator to produce such excellent photographs as are here set forth.

A bacteriological introduction follows the photographic portion and this will prove very useful. It is short—occupying only 14 pages of large print—and admirably clear and explicit, each point as it arises being illustrated by capital photographs.

Next is taken up the life-history of the bacillus anthracis, and that this important organism is adequately treated will be realised when it is mentioned that no less than 10 photographs of its various phases are given. Thus the student is introduced at once to the best-known example of the great group of bacilli and is provided with a typical description to which he can always refer.

Next follow 10 illustrations of the bacillus tuberculosis and afterwards most of the more important organisms are adequately illustrated and described.

Of course, the book does not aim at providing an exhaustive description of the various organisms, but sufficient is given to link the illustrations together and to set forth the more salient points. The paper and print, as is usual with books issued by the Scientific Press, are excellent, and the same may be said of the reproductions of the photographs. On the other hand, the binding is atrocious and much of the usefulness of the book as a laboratory manual is sacrificed on that account. So badly is the volume put together, indeed, that it utterly refuses to remain open at a particular page and any attempt to force it to do so only results in destruction to the book and ruin to the student's temper. This is a subject upon which we have been obliged to speak on former occasions and we notice with regret that the evil is on the increase. The sooner publishers will recognise that it is to their interest to study the convenience of their customers the better it will be for everybody concerned.

The Surgical Complications and Sequels of Typhoid Fever. By W. W. Keen, M.D., LL.D. With five Plates and nine Figures in the text. London: Rebman Publishing Company. 1898. Pp. 386. Price 17s.

This work is based on an analysis of 1700 cases of typhoid fever and practically includes every case published during the 50 years preceding 1896. In this statistical labour the author has been greatly assisted by Dr. T. S. Westcott. In 1876 Dr. Keen gave the Toner lecture at Washington on the Surgical Complications and Sequels of the Continued Fevers; this article is reprinted as an appendix at the end of the present volume, and it will be seen that in it for the first time an elaborate and complete study was presented of the surgical results of enteric fever. The present work is an expansion of this part of the original Toner lecture and is a veritable encyclopædia on the subject. As already hinted this volume does not profess to include all the literature since 1895 and though it covers some of the ground up to January, 1898, it is not absolutely up to date. After a pathological chapter dealing with the bacteriology of typhoid fever and containing numerous references to typhoid infection of different organs without typical intestinal lesions, the author proceeds to a minute consideration of typhoid gangrene, a subject which he had previously taken for his Shattuck lecture in 1896. The sections on the articular and osseous manifestations of typhoid fever contain many interesting deductions; besides typhoidal arthritis properly so-called rheumatic and septic forms may occur in connexion with the disease. In 84 cases of typhoid arthritis dislocation occurred in more than half and nearly always in the hip. With the exception of those of the larynx which are very fully described, the most frequent typhoid sequelæ are met with in the osseous system and of these 237 examples are collected, periostitis (110) and necrosis (85) making up the bulk of the lesions. The reader naturally turns to the valuable and practical section on the operative treatment of intestinal perforation; it there appears that in 83 collected cases where operative measures were adopted 16 recovered, or 19·36 per cent., that the second 12 hours after perforation is the most favourable time for operation, and that after 24 hours there is practically no hope of recovery. An interesting chapter is devoted to the complications of the liver and gall-bladder and Professor Schweinitz has contributed a special article on the ocular complications. In conclusion, we may say that this work must long remain a standard source of reference on the complications and sequelæ of typhoid fever and cannot fail to be of the greatest value not only to surgeons but also to physicians.

LIBRARY TABLE.

The Care of Public Health and the New Fever Hospital in Edinburgh. By James Pollard, C.A., F.S.S. Second edition. Edinburgh: T. and A. Constable. 1898. Pp. 44.—The first record of municipal provision being made by the city of Edinburgh for the protection of the people from disease was in 1497. In that year an epidemic of grandgore or "French pox" broke out and seems to have proved a dreadful scourge; the victims as soon as they were attacked were deported to the adjacent island of Inchkeith where they died in large numbers. In the year of the Scottish defeat at Flodden (1513) there was an outbreak of plague and it is recorded that the town council caused wooden houses to be erected to which the patients were carried. Many things have happened since that time. In 1885 the town council came into possession of the old buildings of the Royal Infirmary and made use of them for the treatment of infectious disease, but the accommodation having been found insufficient a property of 130 acres has recently been acquired outside the city, and of this ground about 40 acres have been set apart for an hospital of 600 beds distributed as follows: scarlet fever, 320 (in seven pavilions); typhoid fever, 80 (in two pavilions); measles, 80 (in two pavilions); typhus, 10; diphtheria, 30; chicken-pox, 20; whooping cough, 20; erysipelas, 30; and probationary, 10. The present description of the new buildings is very complete, and is illustrated by 18 large plates of bird's-eye views, plans, and elevations. Plans of individual wards are drawn on a scale of 25 feet to one inch, which of course shows a great deal of detail.

The Student's Medical Dictionary. By GEORGE M. GOULD, M.D., A.M. Tenth edition. London: H. K. Lewis. 1896. 8vo, pp 701. Price 14*s.*—When a book reaches its tenth edition it is a proof that the work in question is not only a good one but is appreciated as such, two factors which do not by any means always go together. The present book is designed especially for students, and although it will, of course, not take the place of Dr. Gould's monumental work "The Illustrated Medical Dictionary" it will be found to contain everything that a student can want for his average work. A book of this kind is practically an essential for the modern worker since the area of professional literature is constantly being enlarged by new words and phrases. Too much cannot be said in praise of "The Illustrated Medical Dictionary" and we may almost say the same for the Student's Medical Dictionary, except of course that it covers a smaller area of research.

Ambulance Lectures: First Aid to the Injured. By SAM. OSBORN, F.R.C.S. Eng. Fourth edition. London: H. K. Lewis. 1899. Pp. 150. Price 2*s.*—This useful little book has been translated into eight languages, namely, Chinese, French, German, Greek, Italian, Japanese, Spanish, and Hindostani. It consists of six lectures delivered to classes organised under the control of the Order of St. John of Jerusalem and is fully illustrated. The lectures, as beseems discourses delivered to a lay audience, are couched in very simple and practical terms and their scope may be indicated by the author's own words: "Remember that these lectures are not given to make you amateur surgeons, nor to enable you to act independently of professional help, but merely to assist in saving life and relieving pain until that help can be procured." The book is admirably adapted for this purpose and should be of the greatest possible use not only to policemen, railway-men, and the like, but also to travellers.

Dod's Parliamentary Companion, 1899. London: Whittaker and Co. Price 4*s* 6*d*. This useful little book maintains the pitch of excellence to which we are accustomed in former issues. It is well up to date, as may be seen from the fact that the death of the Duke of Northumberland, which occurred on Jan. 2nd, is duly noted. The members of the medical profession in the Houses of Parliament are nine in number—one in the House of Lords, Lord Lister, and eight in the House of Commons, namely, Mr. Ambrose, Sir Charles Cameron, Dr. Farquharson, Sir Walter Foster, Dr. MacDonnell, Sir William Priestley, Dr. Tanner, and Sir Robert Finlay, who although he graduated M.D. left the practice of Medicine for that of the Law.

Whitaker's Titled Persons. London: J. Whitaker and Co. 1899. Price 2*s.* 6*d.*—We have received the third issue of this good little book of reference which has undergone considerable enlargement since its original issue. All titled people are not important and all important people do not (for this reason or that) possess titles, but as a general rule it is a prominent citizen who has titular distinction. Persons with titles are consequently much quoted for their opinions, much employed as figureheads, and are not unknown upon prospectuses, so that it is often necessary for the public to know exactly who they are. In "Titled Persons" we find set down in alphabetical order the name, style, and dignities of all British subjects who have gained or inherited titular distinction. A neat arrangement enables us to sort the cadets of the great families so that we are able to trace back any particular Russell, Campbell, or Stewart to his or her parent stock. A very handy little book.

Sell's Dictionary of the World's Press and Annual of Useful Commercial Knowledge. Vol. I.: Newspaper Section. Pp. 944. Price 4*s.* Vol. II.: Commercial Section. Pp. 692. Price 4*s.* London: Henry Sell. 1899.—Sell's Dictionary of the World's Press makes its nineteenth annual appearance and for the first time in two volumes. Those who remember the modest serviceable little book upon which this great and comprehensive dictionary has been founded may well regard it as an object lesson in evolution. The particular departure of this year's issue is the summarising, primarily for the use of advertisers, of all information likely to be useful with regard to matters of commerce, of navigation, of life insurance, &c. Full particulars of all newspapers published in the United Kingdom are given in vol. i. and for the convenience of those who may require a list of the world's press without referring to that volume a great variety of information relative to home and foreign newspapers is included in vol. ii. No large office or business house can dispense with Sell's Dictionary.

JOURNALS.

Archives Générales de Médecine. Paris. January, 1899.—Four original papers appear in this number. The first is by the late M. V. Hanot on La Cirrhose de Budd or cirrhosis of gastro-intestinal origin by auto-intoxication. The author thinks that this condition is far from being exceptional. The second article is by Dr. A. Brault on the Production of Glycogen in the Tissues which surround Tumours. Well-executed coloured illustrations accompany the text. Dr. M. Kippel writes on the Nervous Symptoms of Cancer. He divides his subject into two main divisions, the symptoms produced by the pressure of the tumour and those dependent on the cachexia. Amongst other clinical phenomena described are the neuro-muscular reaction and debility (lesions of the muscles, the nerves, and the marrow), tachycardia, delirium, &c. This contribution contains much interesting and valuable information. The fourth article, by Dr. Glatenay, is on Acute Osteomyelitis of the Sternum.

The Canadian Journal of Medicine and Surgery. Toronto. January, 1899.—The original contributions in this number include a paper on "Club-Hand" by Dr. B. E. McKenzie. Several cases are detailed, the descriptions being accompanied by some good illustrations. Dr. A. B. Eadie writes on Antitoxin in the Treatment of Diphtheria. He considers that the introduction of antitoxin has robbed this disease of most of its terrors and that if all the patients could be seen early the mortality would certainly sink to a very low point. Dr. A. G. Sherbrooke sends a contribution entitled "Diphtheria with Special Reference to the Laryngeal Cases requiring a Choice between Tracheotomy and Intubation." He considers that both methods have their advantages and disadvantages, but when the operation is possible he prefers intubation. Another interesting communication is by Dr. E. Laberge on Infection and Serotherapy. This paper was read at the Canadian Medical Association, held at Quebec in 1898. Dr. Louis Fischer writes on Therapeutic Suggestions for Children, including Pulmonary Gymnastics. A case of Ectopic Gestation is recorded by Dr. H. E. Vaux, of Brockville, whilst a useful paper on Genito-urinary Instruments required by the General Practitioner is written by Dr. F. C. Valentine, Professor of Genito-urinary Diseases in the New York School of Medicine.

# Analytical Records
FROM
THE LANCET LABORATORY.

IVORY DUST.

(T. PADMORE AND SONS, 118, EDMUND-STREET, BIRMINGHAM.)

IVORY dust is composed chiefly of phosphate of lime and cartilaginous tissue. This specimen gave in our hands the following results on analysis: moisture, 13·31 per cent.; cartilaginous tissue, 28·90 per cent.; mineral matter, 56·00 per cent.; and resinous matter, 1·79 per cent. It yields an excellent white jelly on prolonged boiling with water which is regarded as possessing a high nutritive value. Ivory jelly has been considered from remote time to be a popular restorative; but in view of the above analysis it is doubtful whether it possesses any special nutritive value. It is of course highly nitrogenous, containing an osseous substance analogous to ossein in bone and a very large proportion of bone-producing salt. We are aware that some practitioners, bearing in mind its composition, have prescribed ivory jelly as a food in certain cases and we should be glad to learn whether any distinct physiological or dietetic benefit has resulted.

"SYLVESTER'S" BEEF AND MALT BISCUITS.

(T. W. HOLMES AND CO., 88, WEST-STREET, GATESHEAD-ON-TYNE.)

These biscuits are pleasantly crisp and of good flavour. They evidently contain more malt extract than beef, since the total amount of nitrogenous principles is decidedly lower than might be expected; indeed, they contain a smaller proportion of nitrogenous substances than wheat flour itself. Of course, the addition of beef would contribute considerably to the nitrogenous contents of the biscuits. The mineral matter contained a high proportion of potassium phosphate due to the addition of malt extract. The analysis was as follows: moisture, 10·60 per cent.; nitrogenous matters, 10·26 per cent.; mineral matter, 2·75 per cent.; carbohydrates, with a small quantity of fat, 76·39 per cent. The carbohydrates were largely in the soluble condition owing to the presence of malt sugar. The biscuits would be more satisfactory from the nutritive point of view if a higher proportion of beef substances were added. As it is the analysis indicates very little increased nitrogenous value.

DIGESTIVE TEA.

(JOHN DAWSON, 67, SALISBURY-ROAD, KILBURN.)

We do not believe in "digestive tea." Several processes have been suggested for the treatment of tea, the object of which has been either to remove or neutralise the tannin, but this has seldom been done with success, the delicacy of the flavour and aroma of tea generally suffering. In the present instance the treatment appears to have been with hops. Doubtless to some extent the tannin is rendered insoluble by this means. The infusion has a soft, modified flavour and is quite free from harshness of character even after standing for some time in contact with the treated leaf. The important stimulating alkaloid caffeine is not affected by the process as we extracted from the tea a normal quantity. Possibly this tea would suit some persons who find ordinary tea disturbing to the digestive functions.

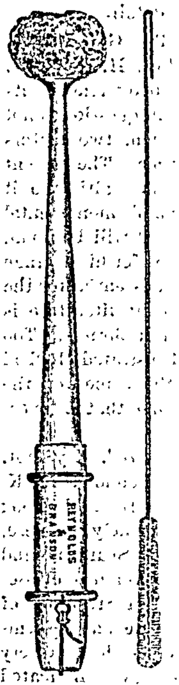
ROYAL COFFEE.

(PAYTON AND CO., TOWER-HILL WAREHOUSE, E.C.)

No admixture of any kind could be detected in the specimen submitted to us. It yielded an infusion of excellent character possessing a full and agreeable flavour characteristic of the aromatic constituents of genuine and well-roasted coffee. These results might be expected considering the somewhat high price of the coffee which is 2*s.* per pound. It is evidently roasted with care, due regard being given to preserving the aromatic and essential constituents of the berry.

New Inventions.

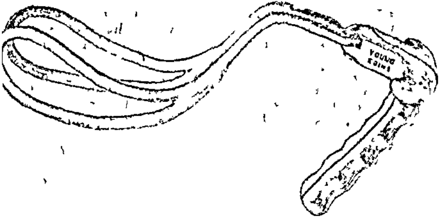
A NEW SPONGE-HOLDER.



AT the suggestion of Mr. H. Bendelack Hewetson, ophthalmic and aural surgeon to the Leeds General Infirmary, Messrs. Reynolds and Branson, of Leeds have made an improved sponge-holder for use in operations on the naso-pharynx where there is a special liability to free hæmorrhage and a consequent necessity for firm and rapid sponging. The stem of the sponge-holder is hollow, and through it is passed a piece of whipcord tied to a small sponge. The two ends of the cord are brought out at the handle, as shown in the illustration, and are tied to a sliding ring, which slips over the graduated handle until it becomes fixed and thereby retains the sponge securely in the slightly trumpet-shaped orifice of the holder, beyond which it projects all round. To enable the instrument to be cleaned and sterilised it is preferably made of celluloid, and is accompanied by a small brush attached to a twisted wire, with a hook at the opposite end for replacing the cord after cleansing. The holder can thus be kept perfectly clean, and it is so simple in its construction that it is not likely to get out of order. The price is 7*s.* 6*d.* in celluloid and 3*s.* 6*d.* in vulcanite. Mr. Hewetson has made various trials with wire, catgut, &c., for fastening the sponge in place of whipcord, but he is inclined to think that whipcord is the best.

A NEW AXIS-TRACTION FORCEPS.

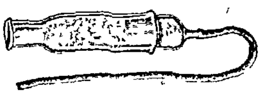
THE accompanying figure shows an axis-traction midwifery forceps suitable for both high and low applications which has proved satisfactory and reliable during a two-years' trial in all classes of cases. The fenestrated portion of the blades and the upper halves of the shanks follow the axis of the parturient canal. The lower halves of the shanks carry the lock and projecting lugs back towards the line of traction of the blades and keep the lock, even in high applications, outside of, and free from, the soft parts. The projecting lugs give the points and direction of traction for the fingers of the right hand. The handles, set at an acute angle to the lock and lugs, shorten the forceps, lie along the perineum, and afford a cross grip for the left hand. They also allow the necessary sweep towards the abdomen of the patient to be made without material loss of power or change of position and enable the right hand to keep up traction, thus freeing the left hand to deal with the head and perineum. In the intervals of traction the handles can be released and the lock loosened with relief of pressure on the cranium and without fear of displacement. The subsequent relocking is simple and easy in all positions. Introduction is greatly facilitated as each half of the forceps is evenly balanced when held in position between the thumb and fingers at the lugs, while the handle projects upwards and backwards. When viewed from before backwards the fenestrated portions of the blades are shorter and the cranial curves greater than the illustration would indicate. I have much pleasure in acknowledging the great care and attention bestowed in the fashioning of the instrument by Messrs. Archibald Young and Son, Edinburgh.



Kilmarnock, N.B. WILLIAM MCALISTER, M.B. Glasg.

ASEPTIC VACCINE EJECTOR.

WE have received from the Association for the Supply of Pure Vaccine Lymph, 12, Pall Mall East, S.W., a convenient appliance to be interposed between a tube of lymph and the lips of the operator who is about to make use of it. The principal feature of the ejector is a plug of cotton-wool contained in a two-part glass tube about two and three-quarter inches long into one end of which the operator blows and the breath, filtered by the cotton-wool, escapes by a slender glass nozzle connected with a soft indiarubber tube about six inches in length. The tube of lymph having been opened in the usual way one end is inserted in this indiarubber tube, the junction is pinched between the finger and thumb, and the lymph is expelled by blowing into the ejector. The price of the ejector is 1*s.* 1*d.* in a case, free by post.



A PIPETTE FOR USE IN ESTIMATING UREA.

THIS pipette is a modification of the one belonging to Southall's apparatus for estimating urea, the rubber nipple at the broad end of the original pipette being replaced by a syringe arrangement which, I have found, greatly facilitates the introduction of the urine into the long limb of the bent tube. Air from the upper part of this pipette is never expelled along with the urine, neither does any urine escape into the hypobromite solution before the nozzle of the pipette is really in the long limb of the decomposition tube. The tube or body of the pipette is about seven and a half inches long and of glass, the nozzle being slightly curved. The movement of the piston is limited by collars on its rod, so that when it is pushed in as far as it will go and then drawn fully out it takes up exactly 1 c.c. The estimation of the urea in a sample of urine is performed as follows. Fill the bent tube with solution of hypobromite of soda just short of overflowing, then gently incline the tube to fill the long limb, then hold the tube in the vertical position and pour in an additional quantity of solution to fill the lower part of the bulb of the short limb. Now take up 1 c.c. of urine in the pipette, pass the curved end of the pipette through the short limb and into the open end of the long limb of the bent tube, and gradually expel the urine. Now draw the pipette out, let the bent tube stand for about half an hour, and then read off the volume of nitrogen gas. The nitrogen evolved by the chemical action of the urea on the hypobromite of soda passes up the long limb and displaces the hypobromite solution downwards. The long limb is marked with an English scale representing grains of urea per ounce of urine, and also with a metric scale representing centigrammes and milligrammes of urea per 1 c.c. of urine. The advantages claimed for this pipette are: (1) that it is accurate; (2) that it is easily worked; (3) that it takes little time; and (4) that it does not waste any hypobromite of soda. Messrs. J. Gardner and Son, Forrest-road, Edinburgh, are the makers.

Edinburgh. C. O. MURISON, L.R.C.P., L.R.C.S. Edin.

FIRST REPORT OF THE ROYAL COMMISSIONERS ON THE METROPOLITAN WATER-SUPPLY.

(Continued from p. 252.)

THE Commissioners report that a consideration of the evidence which they have collected as to the amount of water which can be spared by the Chelsea, Grand Junction, Kent, Lambeth, and West Middlesex Companies shows that the mere connexion of their mains with each other and with those of the Southwark and Vauxhall, New River, and East London Companies would not enable them to be of much assistance in case of emergency arising during the next summer. Such combination would only be effective if the Grand Junction, Lambeth, and West Middlesex Companies were to obtain additional statutory powers for the abstraction of water from the Thames and erect works for its treatment and improved arrangements for pumping.

The New River Company have been able to supply a large quantity of water to the East London Company during the late drought. On July 26th the New River Company reduced the amount of water which they took from the Lee at Ware and left it for the disposal of the East London Company. The water flowed down the river channel to Chingford and thence through the East London intake to the storage reservoirs at Walthamstow. The quantity delivered to the East London Company from July 26th to Oct. 31st, 1898, was 569,082,000 gallons. In order to make up the deficiency the New River Company increased their rate of pumping from the wells. The average amount of water supplied daily by the New River Company to the East London Company during the period mentioned was 5,815,000 gallons daily. The Commissioners point out that this method of giving assistance to the East London Company is very simple and effective and as the water is unfiltered no additional tax is laid on the filtering plant of the New River Company. Connexions have been made between the 30 in. main of the Grand Junction Company in Oxford-street, opposite Poland street, and the 24 in. main of the New River Company at the junction of Rosebery-avenue and Gray's Inn-road, and the West Middlesex Company have effected a junction with the new main made to form the first-mentioned connexion. The Grand Junction and West Middlesex Companies are therefore now able to supply to the New River Company 5,000,000 gallons daily. Such a supply could not, however, be afforded in the summer because those companies could not spare it. The Commissioners point out that the large reserve supply possessed by the New River Company and its wells places it in a more advantageous position than that occupied by the companies previously mentioned.

The Southwark and Vauxhall Company has been able to deliver a large quantity of water to the East London Company during the drought. A connexion was made by carrying a 20 in. main through the Tower Subway in continuation of the 20 in. main of the Southwark and Vauxhall Company. On the Middlesex side a new main was connected with the system of the East London Company. The water was supplied from Nunhead reservoir and the pressure was sufficient to enable the Southwark and Vauxhall Company to supply 6,000,000 gallons a day to the East London Company's district. This arrangement has been rendered possible by a supply of water through a 42 in. main from Hampton to Nunhead and the mains possessed by the company still have a carrying capacity considerably in excess of the requirements of their customers. The Southwark and Vauxhall Company before the year 1897 had a statutory right to draw only 24,500,000 gallons daily from the Thames. During that year an Act was passed and confirmed by a further Act in 1898 authorising an additional abstraction of water to the extent of 20,500,000 gallons a day. An additional amount of 2,250,000 gallons is derived from a well. The amount required for the customers of the company is at present about 37,000,000 gallons daily, thus leaving a surplus of 13,000,000 gallons, but the company is prohibited by its Act of 1898 from selling water to other companies.

The East London Company require increased storage capacity and are at present obviously in no condition to transfer water to other companies.

The fourth section of the report is devoted to a review of the present position of the East London Company and of the measures necessary to ensure a continuous supply of water for their customers. To this question the Commissioners have devoted special attention and have considered the character and extent of the intercommunication of mains which will be necessary to secure a constant supply for East London in case of a drought similar to that which obtained during the year 1898. It is pointed out that the storage reservoirs possessed by the East London Company at Walthamstow are capable of holding 1,200,000,000 gallons, and of this water the greater quantity can be conveyed by gravitation to the filters at their station at Lee Bridge. Some water in the reservoirs, however, could only be utilised by pumping out the lower part of the reservoirs. The amount of this bottom water is 164,000,000 gallons.

TABLE PREPARED BY THE ROYAL COMMISSIONERS GIVING STATISTICS WITH REGARD TO THE WATER-SUPPLY OF THE EAST LONDON WATERWORKS COMPANY.

—	July.	August.	September.	October.	Grand total.
	Gallons.	Gallons.	Gallons.	Gallons.	Gallons.
Required to meet demand in 1899	1,426,000,000	1,395,000,000	1,320,000,000	1,302,000,000	5,443,000,000
Supplies in 1898 from the company's own resources	1,362,326,000	1,094,610,000	743,550,000	716,472,000	3,916,958,000
Estimated deficiency to be met by contributed supplies and by increase in the company's resources	63,674,000	300,390,000	576,450,000	585,528,000	1,526,042,000
Estimated average daily deficiency to be met as above	2,054,000	9,650,000	19,215,000	18,888,000	12,406,000

On June 20th, 1898, the reservoirs of the company were full. On August 22nd they contained 308,000,000 gallons; the directors of the company then restricted the supply to two periods of three hours each daily, and on Sept. 3rd the supply was further limited to two periods of two hours each. On Nov. 23rd a longer daily supply was given; a constant supply to part of the district was resumed on Dec. 7th and to the whole of the district on Dec. 14th. For the year 1899 the Commissioners assume that the New River, the Grand Junction, the West Middlesex, and the Southwark and Vauxhall Companies will be able to contribute to the East London supply in case of need. From the evidence they have taken the Commissioners have come to the conclusion that the estimated deficiency may be met by contributed supplies and an increase in the companies' own resources. In the report a table compiled by the Commissioners is given showing for the four months, July, August, September, and October, (1) the amount of water which they estimate will be required to meet the demand; (2) the amount of water which the company obtained from their own sources during the corresponding months of the year 1898; (3) the estimated deficiency to be met during those months of the present year; and (4) the estimated average daily deficiency to be met. The table is given above.

The Commissioners report that having regard to the fact that the East London Company had been able to carry forward a considerable store of water from the year 1897 to 1898, and that it is possible that they may have no such store to fall back upon in the June of the present year, and having regard also to the fact that there is an increasing annual demand for water, they recommend that arrangements should be made as soon as possible whereby an auxiliary supply of not less than 20,000,000 gallons daily should be made available for distribution in their district. If this amount of water can be made available the system of constant-supply by the company would in their opinion be practically secured for some years to come. The Commissioners point out that these measures should not relieve the company from the obligation of improving as rapidly as possible their own sources of supply so that they may make themselves independent of extraneous assistance. In concluding their report on this branch of the subject the Commissioners point out that if the existing connexion with the Southwark and Vauxhall Company's mains had been made early in the year 1898 and if the fullest available supply had been taken from the New River and from the Southwark and Vauxhall Companies from June 20th of last year a constant supply might have been maintained in the East London Company's district during the whole of last year.

The fifth section of the report is devoted to an account of the views of directors and of the engineers regarding the expediency of adopting a general scheme of intercommunication. Briefly, it is pointed out that the associated companies by their counsel intimated that intercommunication was practicable and convenient, but the evidence given by the engineers of the companies showed that several of them thought that in the case of the companies which they represented no such extraneous help would be likely to be wanted. The evidence of the engineers has already been reported in THE LANCET. The report states that Sir Alexander Binnie, on behalf of the London County Council, gave it as his opinion that it was inexpedient to incur the large expenditure required by Scheme No. 2, because if a new supply were introduced from Wales different arrangements for intercommunication would be suitable and necessary. The conclusion to which the Commissioners themselves have come has been already given. It is to the effect that intercommunication on well-considered lines is necessary from the consumers' point of view.

(To be continued.)

DEATH FROM ANTHRAX.—An inquest was held at the Bristol General Hospital on Jan. 19th upon the body of a haulier, aged 36 years, whose blood contained the anthrax bacillus. The deceased had a sore on his neck which he had probably rubbed against a sack. A verdict of "Death from anthrax poisoning" was returned.

PRIZES OF THE PARIS ACADEMY OF SCIENCES.—The *Revue Scientifique* of Jan. 21st publishes a long list of prizes proposed by the Paris Academy of Sciences for the years 1899, 1900, 1901, and 1903. The prizes in medicine, surgery, and allied subjects are as follows:—Prix Montyon, of 7500 fr. (medicine and surgery). Prix Montyon, of 750 fr. (experimental physiology). Prix Montyon, of 3000 fr. (hygienic improvements in dangerous trades). Prix Barbier, of 2000 fr. (discovery in medical, surgical, or pharmaceutical science, or in medical botany). Prix Bréant, of 100,000 fr. (cure or prevention of cholera). Prix Godard, of 1000 fr. (anatomy, physiology, and pathology of the genito-urinary organs). Prix Serres, of 7500 fr. (application of embryology to physiology and medicine). Prix Chaussier, of 10,000 fr. (application of embryology to physiology and medicine). Prix Bellion, of 1400 fr. (works or discoveries conducive to health or to the improvement of the human race). Prix Mège, of 10,000 fr. (completion of an essay on the progress of medicine). Prix Lallemand, of 1800 fr. (works relative to the nervous system). Prix du Baron Larrey, of 1000 fr. (naval or military medicine, surgery, or hygiene). Prix Pourat, of 1400 fr. (specific characters of the contraction of different muscles). Prix Philippeaux, of 890 fr. (experimental physiology). Prix La Caze, of 10,000 fr. (works or memoirs contributing to the progress of physiology.)

THE LANCET.

LONDON: SATURDAY, FEBRUARY 4, 1899.

THE question as to whether it is or is not desirable that phthisis should be made a notifiable disease has recently been the subject of discussion before different societies; and it is once more dealt with in the address by Dr. ARTHUR NEWSHOLME on the Prevention of Phthisis of which we reproduce a lengthy abstract. Opinion in this matter may be said to be divided in the medical profession, although for the moment it would seem, as far as can be judged, that only a minority favour the proposal. So far as the public are concerned there is but little evidence that they take any particular interest in the question, unless resolutions advocating the notification of phthisis passed by a few sanitary authorities having medical officers of health in favour of the system may be regarded as representative of public opinion in those localities. And, lastly, there is the official attitude towards the subject as represented by the refusal of the Local Government Board to add phthisis to the diseases made notifiable under the Infectious Diseases (Notification) Act, 1889.

As fairly typical of the two sides of the question we may take Dr. NEWSHOLME'S address as setting out the reasons for and the third of Sir RICHARD THORNE'S recent Harben Lectures those against the desirability of making phthisis notifiable in this country. Briefly put, the arguments against the compulsory notification of phthisis have been: (1) that the Act under which it is proposed to effect the notification of infectious diseases was never intended to apply to a disease of long duration such as phthisis, but was limited to diseases having a brief infective stage during which it is no hardship to control the movements and liberty of the individual; (2) that to attempt any such control in the case of phthisis would be likely to interfere with the prospects of phthisical persons who must necessarily during many years of their malady be able to gain a livelihood in order to maintain themselves and often their families also; and (3) that the risk of losing a remunerative occupation and the risk of coming under the control of a sanitary officer would debar many persons suffering from incipient phthisis from seeking medical advice and in this way the object of the notification would be largely frustrated.

The answer to these objections is mainly that under a proper system of notification they would not be likely to arise. Thus, it is said that the notification of phthisis could be made confidential; that the visits to the phthisical person would in most cases consist merely of notices left at the private address of the patient; and, again, that even such limited action as is involved in precautionary measures of this sort should be left almost entirely to the medical attendant and his patient, provided the medical officer of health were informed of each change of address in order to secure the newly coming tenant from the risk of infection left behind by the former occupant. The New York system is again referred to, especially by Dr. ARTHUR RANSOME, an unofficial advocate of the system, who explains that though the data concerning cases of phthisis in private houses and under the care of private physicians in that city are recorded the patients are not in any way interfered with and that even circulars of information are not sent to them except by special request of the attending physician.

Action on these several lines would, of course, involve new legislation in this country, and so far as we are aware this has never before been definitely asked for or even indicated. The demand has been to include phthisis in an Act which has involved and would permit of action of an infinitely more stringent character, and we are more than doubtful whether even the medical profession are prepared to endorse the demand, as it has hitherto been formulated, on a sort of understanding that the medical officer of health is to be the sole judge whether in one and another case of phthisis he shall exercise the powers conferred upon him and upon sanitary authorities as regards infectious disease or not. These powers are very wide indeed, and they were not framed on the assumption that they might be applied to a chronic disease often lasting over a long series of years. In this country the medical officer of health will often, if not generally, be competing for medical practice with the notifiers, and even in those cases of infectious diseases where the power of intervention is limited to a few weeks only instead of being spread over a series of years we cannot say that the medical officer of health has been uniformly judicious. Indeed, the complaints which we have received as to the very objectionable habit on the part of certain medical officers of health of revising the diagnosis of disease made by fellow practitioners and then recommending the non-payment of the notification fees have by no means ceased notwithstanding strong official condemnation of the practice.

Dr. NEWSHOLME, however, implies that personal visits should in all cases be paid by the medical officer of health to ensure the execution of the necessary hygienic precautions. On the other hand, Dr. RANSOME explains that in New York medical inspectors are specially detailed for this work and it is they who give verbal directions and leave circulars of advice. Some such arrangement would, indeed, be absolutely necessary in this country unless a vast number of phthisical patients were left altogether without inspection; indeed, it is quite certain that in populous and widely spread districts, such as are combined for the purposes of the appointment of medical officers of health in many parts of the United Kingdom, the New York system could not be applied without a complete change in our local sanitary administration. It must also be remembered that New York is a single city, not a country, and that we do not yet know the results of the system as regards this limited community where the practice only came into operation so recently as January, 1897.

But, assuming that under some new Act the powers of medical officers of health and of sanitary inspectors are limited to those which alone are justifiable on the basis of the New York experiment, we are by no means clear that in nearly every instance, as suggested by Dr. NEWSHOLME, the necessary inquiries and action could be carried out at the patients' homes instead of at their places of busineto avoid the risk of the loss of employment. Thousands of young adults live in houses of business and a large proportion of the remainder of those engaged in business could only be found in their homes late in the evening. This fact would enormously increase the difficulties of visitations and it is practically incredible that under present circumstances the action taken on notification could in by far the majority of districts have even the pretence of being private and confidential. And if it were not we feel certain that patients once exposed to the results of notification would in a large number of instances studiously avoid seeking medical counsel in the more curable stages of their disease and that the primary purposes of the proposed action would to that extent be frustrated.

Dr. NEWSHOLME urges that there might at least be local option. Local option is generally understood to have relation not so much to the wishes of a dozen town councillors acting under the influence of an able official as to the actual wishes of the majority of the people. If therefore it were distinctly understood before a local election that certain members of a municipality intended to vote for a local Act granting the compulsory notification of phthisis and if under these circumstances a majority favourable to such an Act were returned we could see some justification for the demand in this form. The parallel of other local Acts for the notification of the acute specific fevers is urged in favour of similar local legislation as to phthisis without the conditions which we have named. But the cases are not parallel. The former Acts gave expression to a widespread medical opinion and to a practical unanimity on the part of the public health services, whereas in the case of phthisis this is most certainly not the case. Dr. NEWSHOLME himself records the resolution of the Society of Medical Officers of Health so recently as 1893 to the effect that it was "premature to recommend the compulsory notification of a chronic disease like phthisis." We know of no parallel to this resolution as regards the diseases which now are notifiable, and we feel convinced that with a view of educating the public the first step should be to pass an Act enabling sanitary authorities to pay for the voluntary notification of phthisis. We should then soon learn how far and amongst what classes such notification could be carried on without causing resentment and opposition on the part of the public.

In the meantime no country has performed such splendid work as has been achieved in England and Wales in the reduction of phthisis, and there is still room for much more action in the same direction. To this end it is essentially the private practitioner whose aid it is in giving advice as to the prevention of the disease that must be relied on. Pending some evidence as to much greater unanimity of medical and public opinion in the matter than at present exists we cannot agree with Dr. NEWSHOLME in his free condemnation of the Local Government Board. They can hardly be expected to act on the views of a small minority, however able its individual members may be.

THE discussion upon the Choice of an Anæsthetic recently held at the Society of Anæsthetists, if not wholly satisfying, is at least of considerable interest. Many speakers it is true devoted their energies to the well-worn theme of ether against chloroform but the trend of the discussion was rather towards establishing the position that in the various operations of surgery and in certain well-recognised conditions of patients it is a matter of paramount importance that the anæsthetic should be adapted to the requirements of the individual case. There is no doubt that this fact being once admitted matters of importance become ventilated as side issues but side issues of the first consequence. The position of the practitioner who undertakes the administration of an anæsthetic does not so much now as formerly resemble that of a junior assistant to the surgeon. If we go back a few years when anæsthesia became an accomplished fact we find that almost simultaneously with its inception the anæsthetist sprang into existence. In those days it is true he was an "etherist" at first and subsequently a "chloroformist." That SNOW in his elaborate work and through the brilliance of his experimental researches laid the foundation of the present school of anæsthetists there can be no doubt. SNOW did not *give* chloroform in the sense that he was conveyed by the surgeon to a particular nursing home and told to chloroform his patient. His function, as he recognised it, was to render the patient unconscious with the minimum of risk and with the maximum of comfort to the surgeon. That, we take it, is the ideal which the Society of Anæsthetists placed before itself when it undertook the discussion to which we refer. There can be no doubt that when the anæsthetist recognises the full responsibility under which he labours and is prepared by his experience to do justice to the possibilities of the case he becomes a far more useful personage than the mere rule-of-thumb administrator of chloroform or of ether, as the case may be. Whether such an accomplished addendum to the surgical *entourage* is required is for the public to determine as far as circumstances allow them a voice. We daily find patients more alive both to the discomforts and perils of inexpert anæsthetisation and more keenly sensible to their own requirements and the possibility of satisfying them.

To the surgeon the advantage of having the services of an anæsthetist who is really capable of comprehending the case is not perhaps always recognised but it is undoubtedly great. The anæsthetist if he be a man of experience sees not the practice of one but of many surgeons and so his observation of operations and of the way in which the patients behave under the anæsthetic during their progress is extensive. If, then, in difficult cases the skilled anæsthetist and the surgeon were to discuss the difficult points beforehand there is little doubt that the choice of the anæsthetic would be made with far greater precision and satisfaction to all persons concerned than when it is determined upon hurriedly at the time of the operation either by the anæsthetist or by the surgeon. More especially is this so if the anæsthetist has an opportunity of examining the patient at some period antecedent to the time of operation. As was pointed out at the meeting there are "etherists" who repudiate the use of chloroform and there are "chloroformists" who can see no advantages in the selection of ether. Mere predilection or the surviving superstitions of early professional training should not be allowed to replace the accumulated experience of years of observation and patient labour. All reasoning men whose outlook is sufficiently extended must admit that no universal anæsthetic can be adapted to the hundred and one exigencies of disease in the patient or the multifarious requirements of modern surgery To doggedly insist upon such a theorem is to predetermine failure if not fatality When many speakers insist upon their own views it is hardly to be expected that any unanimity can exist in the conclusion arrived at *How far the danger of chloroform is so much greater* than that of ether cannot at present be accurately gauged In the first place, chloroform is the most extensively employed anæsthetic and is certainly given by persons devoid of special knowledge and often with the most limited experience Secondly, it is alleged by many surgeons both here and abroad that the after effects from ether are more severe and more prolonged than those resulting from chloroform It was, however a noticeable fact in the discussion that with the exception of Sir FELIX SEMON no speaker at the Society of Anæsthetists cited definite cases in support of this contention Roughly speaking it would appear that the anæsthetists as a body favour the employment of ether usually *preceded* by nitrous oxide gas while surgeons prefer chloroform, this preference for chloroform being in many cases due to the fact that the respiration is slowed and rendered more shallow and the blood pressure lowered under that anæsthetic so that movements of breathing and hæmorrhage are both diminished Mr WARRINGTON HAWARD very aptly remarked that not only must the choice of the anæsthetic be considered from the point of view of the surgeon and the point of view of the anæsthetist but also from that of the patient and according to him the patient's first consideration is his individual safety Even here the *matter* is not devoid of difficulty because the personal safety of the patient involves not only his being brought safely through the immediate perils of the operation but also *through* those which occur from such after complications as severe vomiting irritation of the mucous membrane of the respiratory tract and so on

There was unanimity among the speakers that cocaine, at least in the case of children was a drug too uncertain and too dangerous to admit of general application Naturally the subject of local *anæsthesia* by RECLUS'S and SCHLEICH'S methods was spoken of, but as Mr BARKER pointed out our experience at present is slight for any definite opinion to be advanced, although continental opinion is favourable to its use in appropriate cases This discussion will prove of value if it draws attention to the possibilities of modern methods of producing anæsthesia and removes from the confines of empiricism and routine the administration of anæsthetics in the more complicated operations of modern surgery

◆

THE near approach of the meeting of Parliament leads us to ask what will be the bearing of *this session* on the interests of the medical profession and on the furtherance of those ends for the pursuit of which the medical profession exists It may seem to some that between a narrow parochialism which would starve every public provision for the health of communities and a broad imperialism which takes the whole world into its purview, the quiet claims which the science of medicine and its practitioners have on the Legislature have little chance of receiving any adequate consideration, especially in a Parliament so constituted as to give undue voice and weight to the noisiest and least intelligent of the people There is some truth in *these views and too much justification of them in* recent events. But we must not despair. If the representatives of the great art and science, down to its *youngest general practitioner in the remotest parish of* England Ireland, or Scotland, will but steadily work on in the lines of the latest truth and the ripest experience there *is not* a *Parliamentary* constituency or a *Member of* Parliament that will not sooner or later come to confess that the medical profession has a right to be heard in Parliament whenever it presents well considered and well founded recommendations touching the health of the people or its own claims We have still some days to wait for the Queen's Speech and it would be affectation to pretend that we have been let into any secrets concerning the subjects of that important pronouncement But we shall be safe in assuming that two or three questions affecting the public health will be brought to the attention of Parliament and that others may present themselves in the course of the coming session

The first medical subject which occurs to us as claiming the attention of Parliament is that of vaccination The Government may be confidently trusted to remember that the condition on which Lord LISTER'S support and that of many other supporters was given to the remarkable legislation of last year was that in the coming session a *measure for promoting revaccination* should be introduced We give the Government full credit for reluctance in making the concessions which it did make to the conscientious objector, though we can scarcely believe that its members foresaw the immense surprise which their action has excited abroad the keen dissatisfaction which it has occasioned among their own supporters at home, or the feelings of mingled triumph and disrespect which it has produced among those for whose benefit and appeasement it was intended Be this as it may, the law of the land is presumably that children shall be vaccinated and the expectation of that part of the community which is still capable of reasoning is that the Government will place among the urgent business of the Session a measure for promoting revaccination The present calm will not always continue The law of 1898 has multiplied conscientious objectors beyond all expectation But they soon change their minds At Gloucester multitudes of them flocked to the vaccination stations on the outbreak of small pox, and unless all experience is to go for nothing such epidemics will be multiplied on a larger scale The very least that the Government can do is to fulfil the promise of last year with as little delay as possible and in so doing give the best proof it can that those in power remain unshaken in *their belief* that vaccination and plenty of it is the only security of nations against a plague which is as fatal and as hideous as it ever was *Only so can the Government uphold its* remaining credit on this matter and keep terms with the medical profession and the distinguished peer who had such misgivings in *consenting to the* "tremendous experiment" which is now being tried in England.

Another question deeply affecting the health of London is that of the metropolitan water-supply. The Royal Commission is nearing the end of its work—at least, of that part of its work which consists in taking evidence. There is no lack of material in this shape, but the troubles of the Commission will begin when it has to decide between the very sharply divided opinions of practically two sets of witnesses, the one set believing it possible to get all that is needed from the existing supplies provided a better understanding between the companies can be established for mutual help in seasons of drought and difficulty; the other, representing a majority of the London County Council, believing it impossible to meet the growing demands of London out of the present sources and advocating a scheme for bringing additional supplies from Wales or elsewhere. Bills for promoting these rival schemes are before Parliament. The Report of the Royal Commission will be presented ere long and then Parliament will have to discharge one of the weightiest and most difficult duties which it can have to perform in the sphere of domestic legislation.

We may confidently expect also that early in the session the subject of food adulteration will be brought forward for discussion, and it is to be hoped that the present Sale of Food and Drugs Act will be amended in several important respects. Mr. WALTER LONG has stated that he is to be responsible for the introduction of the new Bill.

Other questions with a medical bearing or affecting the health of the people are likely to arise. The recent trials for the crime of producing abortion have brought to light a state of the law which tends to hinder conviction, and it is probable that the Government itself will see the necessity of proposing a change. The change is the more urgent as there is much reason to believe that the crime is more common than is generally supposed. The new lights on tuberculosis and the ways in which it is originated and spread lead many to think that legislation should be invoked for its notification and for enforcing measures for its prevention. But the language of Lord SALISBURY at the meeting at Marlborough House—of which public opinion seemed to approve—was in favour of relying more on the spread of public intelligence. One measure seems to be loudly and generally called for—the establishment of public abattoirs where the slaughter of animals can be conducted with the greatest attention to hygienic and humane considerations and by which the detection of disease would be most facilitated. We may hope that in the course of the session the Royal Commission on the Licensing Laws will make its report, but it is not at all sure that this will be done soon enough to enable the Government to propose legislation on a question so profoundly affecting public health and morals as well as the pecuniary interests of a large and powerful trade. The Government which has given us the Inebriates Act, 1898, may be looked to for such improvements in the licensing system as will tend to diminish the number of inebriates.

It is scarcely probable that any legislation directly affecting the medical profession or its organisation and discipline will be asked for or attempted this session. The General Medical Council does not meet till May, and it has not yet made up its own mind as to what is needed and what is practicable. There are many reasons why the Council should try to come to some practicable conclusions on these subjects and that without much more delay. The Midwives Bill will again be presented to Parliament with some additional claims to attention, but it remains to be seen whether it can be fully adapted to the views of the General Medical Council as suggested by the Lord President. And even if the General Medical Council be satisfied the profession at large may not be.

Annotations.

"Ne quid nimis."

THE MODERN MIDWIFE.

ON Jan. 27th an inquest was held at Lincoln by the coroner, Mr. Trotter, upon the body of an infant, aged 20 days, who died on Jan. 25th. The child in question was one of twins, was weakly from birth, and was said to have suffered from convulsions, but no medical man was called in because the nurse in attendance said, according to the evidence of the father, that no doctor was necessary, for no one could do more than she, the nurse, was doing. Nurse Southwell, who gave evidence, said that she was a trained nurse of the Maternity Society. She argued that no medical man could do more than she had done, but she had told the mother if she was not satisfied to call one in. She knew from the first that the child would not live and she told the parents that if anything happened during the night she would give them a note to say that the child died from convulsions. The coroner here asked if the witness thought it her duty to say that a case was hopeless without having her opinion backed by a medical man. The witness replied that she had done it in other cases repeatedly, that when she was in training she did the same thing, and had always understood that she was quite at liberty to do so. She then asked the coroner what she should do, for "when we send for a medical man to see an immature child he refuses to come." Dr. McFarland said that the child was very small but not premature in his opinion. Death was due to wasting and he thought that certainly a medical man should have been called in. If parents were told that a child was certain to die they naturally became careless and hopeless. The jury returned a verdict of "Death from natural causes," adding a rider that Nurse Southwell had exceeded her duties and ought to be censured. The coroner accordingly called her into the room and severely reprimanded her. We do not know what the Maternity Society to which this woman referred may be, but we hope that it is not the Lincolnshire Nursing Association; neither do we believe that any responsible training institution would allow their nurses to act as Nurse Southwell suggested that she had been allowed to do and trained to do. The impropriety of her behaviour passes all bounds, but there is unfortunately no way in which she can be punished.

THE METROPOLITAN ASYLUMS BOARD.

AT the fortnightly meeting of the Board on Jan. 28th a slight decrease in the number of cases under treatment—43—was reported. Of the cases 2690 were scarlet fever, 1323 were diphtheria, one was typhus fever, and 248 were enteric fever. There was not one case of small-pox under treatment. A decrease had occurred in the notifications to the Board of 170, the number being 1650, as against 1820 in the previous fortnight. The leaps and bounds with which the work of these hospitals is increasing is well brought out in a discussion on a motion to raise the salary of the excellent clerk to the Board, Mr T Duncombe Mann, to £1250. The hospitals have increased in the eight years of Mr Mann's service from eight to 14 in number; the staff from 1800 to 3700. In the eight years preceding Mr Mann's appointment 35,000 patients were treated, in the succeeding eight years 141,000. This does not show that the infectious diseases of London have increased in amount—though we should like some facts on this head—but that the objection to send them to the hospitals is diminishing and perhaps that the regulations for excluding the unfit are not very strong.

THE PATHOLOGY OF ERYTHROMELALGIA

IN 1872 Dr Weir Mitchell described "red neuralgia" or erythromelalgia. A number of theories have been put forward of the pathology of the disease, which is generally regarded as of nervous origin. Lewin and Benda published a paper in the *Berliner Klinische Wochenschrift*, 1894, in which they collected 41 cases. They concluded that erythromelalgia was not a disease but a manifestation of various cerebral and spinal maladies. In THE LANCET of August 13th, 1898, Dr James Collier published a most important article showing that erythromelalgia occurred in a number of nervous diseases—disseminated sclerosis, tabes, neurasthenia, and myelitis—and that it was not a rare symptom of spinal cord disease. In the *American Journal of Medical Sciences*, January, 1899, Dr Weir Mitchell and Dr Spiller have published the following important case, the only one in which microscopical examination of affected parts has been made and peripheral disease of nerves and arteries found. A man, aged sixty one years, in fair health, began to have limited areas of severe pain in the right foot with tenderness and flushing when the limb hung down. Whilst the fourth and fifth toes were thus affected a small, deep, painful ulcer appeared on the outside of the fourth toe and healed slowly. After three months these toes seemed nearly well and the second and third were furiously attacked. As these improved the great toe was affected. Cold and elevation relieved the pain, heat and depression made it worse, walking was unendurable. The great toe was slightly red but not swollen. The heart was feeble, the arteries were soft, and there was no excess of tension. The circulation in the left leg was good but in the right a pulse could not be felt below the groin. Many remedies were tried in vain. The toe and half the metatarsal bone were amputated. The wound healed slowly with some sloughing. After the operation the patient had pain in the ball of the foot and some reddening of the toes, but he was better. The nerves of the great toe were intensely degenerated and showed scarcely any nerve fibres consisting almost entirely of connective tissue. The media and intima of good sized vessels were greatly thickened, in some places the lumen was nearly obliterated. The bones were enlarged. In a case of erythromelalgia of the lower limbs reported by Auerbach the nerves were normal (but it is not certain that the most peripheral parts were examined), the upper sacral and lower lumbar posterior roots which supplied the affected parts were much degenerated. Auerbach found that a patient recovering from multiple neuritis presented deep redness of the legs and feet after they were hung down for a few seconds. Dr Weir Mitchell held that erythromelalgia may be due to spinal disorder, but more recently he has been inclined to attribute it to neuritis. The preservation of sensation in the great toe in his case is striking, the few scattered undegenerated fibres must have been sufficient for transmission. The writers conclude that in their case the symptoms were due to peripheral neuritis, but inasmuch as such was absent in Auerbach's case it follows that involvement of sensory fibres anywhere between the cord and the periphery, and possibly within the cord, is capable of causing erythromelalgia. But they are unable to say whether the arterio sclerosis or the neuritis in their case was the primary lesion, as it is exceedingly probable that such disease of the vessels would affect the nerves.

THE NEW BRITISH SERVICE BULLET.

PROFESSOR BRUNS of Tubingen, who had previously investigated the effects of the Dum Dum bullet, has been recently experimenting with the new British service rifle bullet. He finds, according to a correspondent's report published in the *Standard*, that the new bullet causes severe wounds at short distances, but cannot penetrate strong screens or four or five persons. It may, he thinks, be very effective in wars with savage tribes, but would probably prove less so in European warfare, in which shots are exchanged at 1000 to 1500 metres and the decisive firing is mostly at 500 metres—that is, at a distance at which the distinctive effect of the new bullet does not take place. At short ranges the bullet is easily altered in form, the greatest change in this respect taking place in the case of its being fired into moist and liquid substances. The penetrative effect is diminished, the lateral increased, and this causes a greater destruction of the object hit in proportion to the greater diameter of the bullet. Shots striking soft parts at 25 to 50 metres have a decidedly more severe effect than with other bullets, though not nearly so destructive as those tipped with lead. At the maximum velocity they burst in the muscles and their effect in the hollow organs which are filled with fluids is almost unexampled. Shots through the bones are also more destructive at the above mentioned distances than those of other bullets and almost as destructive as those that are lead tipped. The bullet is always broken into small fragments. At distances of 200 to 400 metres also the fractures of bone are decidedly worse than with other bullets though the difference is not so great, whereas at 600 metres there is hardly any difference.

VENTILATION AND SANITATION OF THEATRES AND CHURCHES

A DISCUSSION on this subject of much moment to the general public has been recently carried on in some of the medical and lay papers of New York City. The starting point of the remarks was a paper read by Mr William Paul Gerhard, C E, before the meeting of the American Public Health Association held in Ottawa last September. Mr Gerhard selected the Hygiene of Theatres as his topic and avers that with the exception of a few recent metropolitan theatres the arrangements for the comfort and health of theatre goers, of actors, and stage employes are seldom considered, and he arraigns the conduct of places of amusement in the following scathing terms. "It is a well known fact that there are vast numbers of persons who, while they would thoroughly enjoy a good play, are restrained from visiting such places of amusement for the very good reason that they fear the exposure to the stifling, noxious overheated atmosphere of the buildings, and who are sure if they do go to awake the next morning with a severe headache or with a cold or sore-throat contracted through exposure to draughts. The whole question of the sanitation of theatres is then entered into in detail. The *New York Medical Record* of Jan 7th makes Mr Gerhard's paper the text of a leading article and wholly agrees with his views on the matter. This article says. "The hygienic arrangements of theatres and other places of amusement are all the world over disgracefully neglected. The importance of the thorough sanitation of schools and similar institutions is now fully realised and no expense or trouble is grudged in carefully looking after the bodily as well as the mental welfare of the young. ...... It is therefore decidedly curious that the greater portion of the adult members of the community exhibit a complete indifference toward matters hygienic in connexion with theatres and music-halls. One reason for their careless disregard of the laws of health is without doubt owing to the fact that a stay in a place of amusement is necessarily brief and that so long as attention is paid to pleasing the eye and ear it appears to be a question of small moment whether the air is healthy or foul. Nevertheless, there are signs that the general public is becoming more alive to the dangers lurking in theatres and establishments of a like nature and it is probable that in the near future the construction of buildings devoted to the pursuit of pleasure will be conducted with a due regard to the health of their patrons." Our American contemporary in the same article criticises the sanitary methods of churches, and particularly of Roman Catholic houses of worship, pointing out that masses are held in them at frequent intervals at which all sorts and conditions of people are present and that at a church, as at a theatre, it is impossible to provide a sufficient allowance of pure air by means of windows or other openings and recommends as the only effective alternative both for churches and places of amusement the mechanical method by propulsion, giving an allowance of about 1800 cubic feet of pure atmosphere per hour for each individual. In the Sunday edition of the *New York Sun* of Jan. 8th a leading article is published dealing with the remarks of the *New York Medical Record* so far as the sanitation of churches is concerned, which, while allowing that overcrowding may occur in Roman Catholic churches, is somewhat sceptical as to the truth of the application to churches of other denominations. In fact, the *New York Sun* asserts that in New York at least it is rather the other way of too small attendance, bringing forward in support of this contention the statement of one of the most renowned preachers of the city, the Rev. Dr. Rainsford, who only recently made the complaint that nowadays instead of attending church the larger number, not only of young men but of family men, take their bicycles or their golf clubs and go to the country. However, whether this be so or not is beside the point. It appears to have been shown without a doubt that in New York and in the United States generally the theatres, concert-halls, and many of the Roman Catholic churches are both overcrowded and ill-ventilated. We have in THE LANCET on more than one occasion drawn attention to the ineffective hygienic arrangements and overcrowding of London places of worship and it may be said that although some of its theatres are satisfactory in these respects, yet, that many are susceptible of much improvement. We trust nevertheless that no one of them is in such a condition as the theatre in New York alluded to by Mr. Gerhard in his afore-mentioned paper "where each time the curtain rises a strong whiff of sewer air greets the audience." That sanitary reforms alike in theatres, music-halls, and churches would, either in America or Great Britain, be beneficial to the health of their audiences and in the long run, at any rate in the case of places of amusement, satisfactory to the pockets of their proprietors is a truth not to be gainsaid.

SANITATION AT PORTO RICO.

AT Porto Rico, as at Havana and throughout Cuba, the Americans are face to face with sanitary problems fraught with no ordinary complications. At Porto Rico the first difficulty, for instance, is as to how a sanitary authority is to be constituted. General Henry is in command on behalf of the American Government, but he has to establish some form of local self-government. According to the Spanish law every man, however ignorant, would have the right to vote. On the other hand, if the suffrage was restricted to those who could read and write, this would disfranchise 85 per cent. of the population and place local administrative questions in the hands of a privileged minority. General Henry proposes to avoid these two extremes by allowing all who pay taxes and all who can read and write to vote. But, however the authority is constituted, it is certain that the native population is not capable of settling the sanitary problems. The Americans alone possess the necessary experience and knowledge for dealing properly and thoroughly with these matters. At first sight the capital of Porto Rico, San Juan, seems a clean town, for the streets are well paved and swept, but the interior courts and back alleys are filthy. Where the houses have two storeys the first floors, being notoriously more unhealthy, are either let for shops or stores or to poor tenants. The poorer classes are for the most part negroes. The real remedy would be to remove them to the outlying country districts. They crowd the dwellings to a terrible extent. There is no drainage and no proper room for them to wash their clothes. On all sides—in the passages, on the stairs, and in the rooms—damp linen is hung up to dry and pails of foul water in which the clothes have been washed abound. The water used for all purposes is rain-water collected from the roofs and kept in underground cisterns where it is frequently contaminated. There are no public latrines or washhouses in the town. Then the atmosphere is still further poisoned by small portable charcoal stoves which do not communicate with chimneys, but are placed anywhere on the floor and lighted for cooking purposes. On all sides, naked children may be seen playing amid the dirty surroundings. Though the second-floor tenements are healthier they suffer from the foul odours generated on the first-floor. The negro, however, does not object to these conditions and will put up with any inconvenience so as to be able to remain in town. It is quite certain that he will not voluntarily remove to a healthy suburb. Nor will his landlord make the slightest effort to get rid of him. The poorest tenements give the best return on the capital invested, and the owners of such property will energetically resist all attempt at reform. But this obstacle exists everywhere—in Europe as well as in America. There is, however, one favourable circumstance at San Juan—the fall is good and natural drainage could be secured. The Spaniards also have nearly completed an aqueduct to bring pure water from the country. Unfortunately the pipes which they employed will only bear a pressure of 75 lb., whereas for a proper distribution they should be able to resist at least double such a pressure. The water-supply system has therefore to be completed and improved; sewers must be built, and if the first-floor negro tenants are allowed to remain public washhouses must be provided for them where their linen can be washed in a convenient and cleanly manner, and regulations against overcrowding should be strictly enforced by law. Such measures should be welcomed by the inhabitants, but in their present state of ignorance they are more likely to excite opposition than approbation.

THE GENERAL EDUCATION OF THE MEDICAL PRACTITIONER.

A CORRESPONDENT sends us a somewhat discursive communication dealing with a number of subjects, but his remarks upon the position of the general practitioner are sensible. He calls to mind the fact that sundry specialists—notably Professor Edgar—think that the "majority of practitioners know little or nothing of gynæcology ...... and hundreds more (women) lose their lives simply because the diseases which have carried them off are not recognised in time." Not only the gynæcologist has to complain of want of knowledge on the part of the general practitioner but other consultants and even laymen Mr Arthur Chamberlain is reported as saying. "The desire is not to get cheap advice, but for the most part the people I am referring to have been paying a general practitioner for a long time directly or indirectly, through clubs or in other ways, but not having been cured and perhaps not having had their ailments correctly diagnosed they go to the hospital in the hope of getting a definite opinion from the highest medical authority" So far our correspondent He considers that a great deal too much attention is paid to lectures and not nearly enough to practical work—a contention which is in some ways, we think, justified As to the conditions under which general practice is carried on he says that the well-to-do patronise the specialist and the hospital physician who "plays the double part of consultant and high class medical practitioner" The working classes patronise medical aid societies and penny a week clubs No one, thinks our correspondent, should be permitted to accept less than the minimum fees of 2s 6d and 21s He concludes by saying. "It might well be said that the pecuniary interests of the teaching and examining bodies appear to be much safer in the hands of the General Medical Council than are the vital and sanitary interests of the British public" One medical protection association at least has adopted the principle of binding its members to accept no less than a minimum fee, the sum being slightly lower than that mentioned by our correspondent A monopoly of practice will never be granted to medical men but something will have to be done to make unqualified practice more difficult It is not illegal, but we do not see why its practitioners should not be made to pay a heavy fine for the privilege of being allowed to treat their patients—i e, should have to pay a large sum for a licence, renewable every year and revocable without notice, while anyone found practising without a licence should be liable to imprisonment with hard labour on conviction

"THE PREVENTION OF TUBERCULOUS DISEASE"

DR ALBERT S ASHMEAD of New York has a grievance and has written to us at some length on the subject He says "I have often had the experience that things which have been observed and studied carefully, and then written about by Americans and published not in one place but in two and even three appear suddenly in some continental journal or society meeting as if an entirely new idea had just originated in the mind of some medical Sir Knight and was now seeing the light of day for the first time in a European paper. Is it not time that it should be understood that the American Union has not only made its appearance as a world power, but also one of the leaders of medical thought?" We quote Dr Ashmead's own words because we are not quite sure what he *means*, but we think that *his American* colleagues will hardly thank him for writing in such a strain. We should like to know what the "American Union" is, for instance, and whom he accuses of plagiarising, and what the unknown has plagiarised Dr Ashmead has read in the *Sun* (New York) an account of Sir William Broadbent's remarks at the recent meeting at the Mansion House and Sir Richard Thorne's Harben Lectures He has also read our leading article of Dec 3rd, 1898, on the subject of the prevention of tuberculous disease As an answer apparently to all this he *sends* us a paper written *by himself* and published in *Science*, vol xx, No 506 (1892), on "The Absence of Cow's Milk from Japan and its Beneficial Consequences" We have carefully read the paper but cannot quite associate its tenets with those held by the English observers already mentioned He first makes the extraordinary statement that the reason for the absence of rachitism from the Japanese race is because cow's milk is never given to children, they deriving liquid nourishment from their mothers until the age of six years, and then says that tuberculosis is very far from being absent from Japan He apparently intends to show that he proved in 1892 that milk has nothing to do with tuberculosis, for although milk is never taken in Japan yet tuberculosis exists Could any argument be weaker? If he had said that milk is not taken and the race is therefore free from intestinal tuberculosis we could understand him, but to make such remarks as we have quoted on such grounds cannot add support to his contentions

DEATH UNDER CHLOROFORM

JESSE COOK, aged 38 years, died from the effects of chloroform in the workhouse hospital of Fir Vale, Sheffield, on Dec 7th, 1898 The man required a slight operation upon one of his knees and for this purpose chloroform was administered from lint by a junior medical officer, one drachm, *it is stated, being used* *The patient was in the stage* of excitement (third degree of narcotism of Snow) when respiration failed Mr C Black, who has courteously supplied us with notes of the case, believed that death was due to "paralysis of the respiratory centre, although the verdict arrived at by the coroner's court was "Death from syncope caused by the administration of chloroform" The *two conditions are very different* indeed and need the most careful differentiation As has been pointed out again and again in our columns the smallness of the dose has little bearing upon the mechanism of the death, It is the rate of evaporation and of absorption of the drug which produces death In Snow's experiments in one case he gave *to a cat a 4 per cent.* vapour of chloroform and in 16 minutes *respiration* ceased although the heart did still beat. In others he gave 10 per cent, using small quantities in each case In half a minute insensibility was present, in a minute respiration grew difficult and the heart's action became weak; and in between three and four minutes respiration and circulation *had ceased* Now, as Snow points out, in the first case when the vapour used was comparatively weak the death occurred gradually, "The breathing was arrested by the influence of the chloroform on the nervous centres, but the heart continued until it was stopped or very nearly so for want of respiration, as in asphyxia from privation of air" In the other cases "the action of the heart was *arrested* by the direct effect of the chloroform, in one instance at the same moment as the respiration and in the other even before it" Surely *no two modes of death can* be more distinct, and their confusion is most disastrous, since in the one instance the patient can practically always be saved if the condition is *recognised and* artificial respiration is at once applied, while in the other the patient can seldom be brought round In the Fir Vale case no doubt during struggling the patient's forced breathing led to an increased chloroform vapour tension in the lungs and a fatal overdose was taken

THE LIVERPOOL SCHOOL OF TROPICAL DISEASES IN CONNEXION WITH UNIVERSITY COLLEGE, LIVERPOOL, AND THE ROYAL SOUTHERN HOSPITAL

IN a letter dated Nov 9th, 1898 published in the London papers the *Secretary of State for the Colonies* pointed out that the Medical School of University College, Liverpool, and others situated in large seaports, possess exceptional facilities for the study of tropical [illegible] Stimulated by this and considering the [illegible] prevalence of tropical diseases, knowing also the very large number of such cases which find their way to Liverpool, owing to the connexion of that city with the trade of West Africa and other tropical countries, and taking into consideration that the Royal Southern Hospital and the newly-opened Thompson-Yates Laboratories of Physiology and Pathology offered every facility for teaching and research, Mr. Alfred L. Jones of Liverpool generously came forward and offered to support the movement for founding a school for tropical diseases in Liverpool by an annual grant of £350, suggesting the formation of a committee to consider the best mode of inaugurating such a scheme. The port of Liverpool offers very great advantages for the investigation of tropical diseases. Some of the largest steamship liners in the country keep up constant communication with Africa, South America, and the East, the intercommunication with West Africa being especially great. The Royal Southern Hospital from its close proximity to the docks has annually treated large numbers of patients suffering from malarial and other tropical affections. In recent times the Government subsidised a number of beds in the hospital for the use of soldiers returned from the Ashanti war. Pending the erection of a new block one floor of the hospital will be set exclusively apart for the study of tropical diseases. This consists of a well-ventilated and well-lighted ward which will contain 20 beds and of an adjacent capacious ward laboratory for the examination of blood, urine, fæces, and other excreta. This laboratory will be furnished with the apparatus applicable to modern clinical research. The Thompson-Yates laboratories are situated within easy reach of the hospital; a full description of them was given in The Lancet of Oct. 1st and 8th, 1898. There will be a special lectureship in tropical diseases in the new school at a salary of £250 per annum and it is hoped to obtain for the purpose the services of a gentleman who has devoted his life to the study of tropical diseases and who will not be debarred from private practice. Further particulars as to this appointment will be found in our advertisement columns. His lectures will be illustrated by lantern slides, diagrams, and reference to the cases in the tropical diseases ward. There will also be a demonstrator of tropical pathology whose time will be wholly devoted to that subject and who will teach both in the ward laboratory and in the Thompson-Yates laboratory. As many gentlemen who intend to take up the study of tropical diseases will probably come from a distance it is proposed to offer special residential accommodation in the Royal Southern Hospital. The foundation of schools devoted to tropical diseases cannot fail to give a fresh impetus to the study of this important branch of medicine. Medical men before proceeding to the colonies or taking medical charge of ships can in future thus obtain a complete course of instruction in tropical medicine. We are glad to be able to announce that the income of the new school is already £900 a year.

LIQUID HYDROGEN.

On Jan. 20th Professor Dewar gave a lecture at the Royal Institution upon liquid hydrogen. In the course of his opening remarks he said that he hoped to be able to exhibit some liquid hydrogen in the course of the evening but that he doubted whether he should, for some 10,000 things might happen to prevent it. Pressure and cold were the two agents employed in liquefying hydrogen. The first gas to yield was chlorine, which was obtained as a liquid by Faraday and the pioneers in the reduction of the more refractory gases were Andrews, Graham, Pictet and Cailletet, and Olszewski. At this point of his discourse Professor Dewar received a message from the laboratory. He then remarked, "Just what I expected, the tap through which the liquid hydrogen was running is blocked by a lump of frozen air." This to an audience largely composed of persons other than purely scientific men and women might have been considered somewhat startling, but owing, we suppose, to the genius loci, nobody exhibited more surprise than if Professor Dewar had remarked that an ordinary water-tap was frozen. Proceeding with the account of hydrogen Professor Dewar said that its boiling point was – 240° C., or about 30 degrees of absolute temperature. Its chief use at present was to make high vacuum tubes which it did almost instantaneously by condensing the air into a liquid. With regard to its properties it exhibited a well-marked meniscus, capillarity, no appearance of a metal, and would not conduct electricity. Professor Dewar concluded by expressing a hope that at a future lecture he would be more fortunate and would be able to show some of this newest liquid.

PRESENTATION TO DR. COUPLAND.

On Jan. 28th a numerous gathering assembled in the large lecture theatre of the Middlesex Hospital Medical School on the occasion of a presentation to Dr. Sidney Coupland on his severing his active connexion with the hospital and medical school in virtue of his appointment as a Commissioner in Lunacy. The presentation consisted of a set of table silver, comprising candlesticks, salt-cellars, salvers, and bowl, all designed in the style of the best period, the bowl bearing the inscription: "To Sidney Coupland, M.D., F.R.C.P., from his colleagues, pupils, and friends at the Middlesex Hospital, 1872–1898;" together with a diamond and sapphire pendant for Mrs. Coupland. Dr. Cayley in making the presentation spoke in eloquent terms of the zeal and unselfishness which Dr. Coupland had always shown to the hospital and school throughout the number of years during which he had been connected with them. Dr. Coupland, speaking with evident emotion, thanked Dr. Cayley and those friends who had interested themselves in the presentation and referred to the devotion he felt towards the hospital and the grief which it caused him to cease his active work on its staff. After the ceremony the visitors had an opportunity of inspecting the new school buildings which had just been completed, the well-equipped and appointed laboratories of which fully bring it up to all the requirements of modern medical study.

HOSPITAL ABUSE AND THE ABUSE OF FRIENDLY SOCIETIES IN AUSTRALIA.

It is to be gathered from the letters of our special correspondent in Australia that hospitals and friendly societies are liable to the same abuses which call for such loud complaint at home. The expenditure of the Melbourne Hospital under all items increases. Probably but little care is taken to exclude the unfit, for we note that the daily average of cases has increased in two years by 24 and coincidentally the number of operations. A sub-committee of the hospital appointed to investigate this evil and to find a remedy for it has arrived at some remarkable conclusions, one of which seems quite original, and—supposing the patients to be rightly admitted as fit subjects for hospital help—very cruel. Visitors to patients are to be charged sixpence a ticket for admission as if they were visiting an exhibition. This is an ingenious device, but not very creditable to a charitable institution. In-patients as well as out-patients are to be charged a registration fee; the contract system has to be extended to all departments; and students are to be more heavily taxed by paying annual fees as well as entrance fees. The one conspicuously proper remedy for this evil—the exclusion of the unfit—is not even mentioned. We venture to suggest to the authorities the reconsideration of the charge on the really poor for visiting their friends and the establishment of an efficient system for excluding the unfit. A far larger number of cases of disease can be treated at home than is generally supposed and the indiscriminate admission of people to the out-patient or in-patient department tends to exaggerate the error. The relations between the medical profession and friendly societies have been under discussion at a conference of delegates from the medical societies of the colonies and some resolutions were passed which will be studied at home with interest. It was agreed that the societies should impose a wage limit of £200 per annum upon all their members; that each member of a lodge should pay an annual fee of 10*s.* and a fee of 1*s.* for each consultation and 2*s.* 6*d.* for each visit of the lodge surgeon; and that midwifery, miscarriages, anæsthetics, operations, and cases involving legal proceedings should be extras. From the information already collected by the Medical Defence Union of Australia, at whose instance the conference has been held, it is clear that the abuse of friendly societies by well-to-do people is very prevalent. One suggestion is very good, that a conference should be held between delegates of the medical profession and delegates of the friendly societies. This is the likeliest way of getting any real improvement and until it has failed other measures should be postponed. Public opinion will be much more in sympathy with those seeking the correction of abuses if they are first amicably discussed between the parties most interested. We are glad that the proposal for such a conference has emanated from the medical profession.

HELIOTHERAPY *ALIAS* PHACOTHERAPY.

"IT was in the beginning of the month of September last that I conceived a therapeutic process which seems to me to be new." Such are the opening words of a communication which was made by M. Pierre Apéry of Constantinople to the Société Française d'Hygiène, the occasion being an ordinary meeting of that body on Dec. 9th, 1898. The duration of the gestatory period cannot but strike the professional reader as perilously brief, but it is to be hoped nevertheless that M. Apéry's offspring may not prove to be an abortion after the fashion, alas, of so many other therapeutic novelties. Archimedes, we believe, was the first to make use of burning-glasses, but whereas the Syracusan mathematician employed them for a destructive purpose the Ottoman observer hopes by their instrumentality to put an end to disease. Having offered some rather desultory remarks on the ancient and modern employment of heat in medicine M. Apéry continues as follows: "A goodly number of infectious affections undergo a salutary modification when exposed to the influence of solar light. The micro-organisms which rightly or wrongly are regarded as *the factors of* diseases, do they not recognise the direct light of the sun as their greatest enemy? It is well known that, among others, the microbe of tuberculosis fades away more readily, and perhaps more rapidly, under the direct action of solar rays than it does through the agency of the so-called antiseptic preparations. These are the considerations which have induced me to present to you to-day a new process for the treatment of a series of disorders that are amenable to light and heat. My method consists in the concentration of solar rays by means of a converging lens and consequently in the formation of an intensely calorific and luminous focus." Among the diseases on which M. Apéry proposes to operate with his burning-glasses are some "reputed incurable," such as cancers, tuberculous ulcerations, &c., and he also is of opinion that the process is peculiarly applicable to the bites of sick or venomous animals. "In fact, wherever the destruction of a parasite is indicated, or that of a noxious microbe together with its secretions and toxins, phacotherapy can be adopted with confidence, the invasion of the tissues by the micro-organisms and the pullulation of the latter therein being in this way effectually prevented." In addition to phacotherapy, which consists essentially in the transmission of solar light and heat through lenses in a concentrated form, M. Apéry also indicates spectrotherapy as a therapeutic medium. The prismatically decomposed rays are sure, he thinks, to prove useful in certain pathological conditions, but as yet he has not been able to investigate the matter sufficiently. Doubtless in a few cases, and especially among travellers and explorers, cauterisation by means of a burning-glass might be employed advantageously, but M. Apéry must not flatter himself that he is the first in this particular field. If he will take the trouble to refer to Pliny he will find a passage to the following effect: "These are balls or globes of crystal or glass which being exposed to the sun transmit a heat sufficient to set fire to cloth or *corrode the dead flesh of those patients who stand in need of caustics.*"

THE PUBLIC HEALTH OF MALTA.

WE *have just received* the report of the Public Health Department of Malta for the year 1897, compiled by Dr. S. Pisani, chief Government Medical Officer. The estimated population on Jan. 1st, 1897, of the islands of Malta and Gozo was 157,736 and 20,009 respectively. The number of births in the two islands in 1897 was 6019 and the number of deaths was 5547; the birth-rate per 1000 living was therefore 38 and the general death-rate 31·8 per 1000. The death-rate of both islands was 25 2 per 1000 in 1895 and 7 8 per 1000 in 1896, the steady increase being due to an extremely high infant mortality. The disease which is most destructive to infant life in Malta is enteritis. The percentage of deaths under five years to total deaths was for Malta and Gozo 50 6 in 1895, 52 9 in 1896, and 61·3 in 1897. The general list of deaths includes three from small-pox, 189 from measles, three from scarlet fever, 76 from whooping-cough, two from diphtheria, 82 from enteric fever, 53 from dysentery, 62 from remittent fever, 440 from various forms of tubercle, eight from leprosy, 164 from apoplexy, 473 from cardiopathy, 377 from bronchitis, 431 from diarrhœa, and 933 from enteritis. The water-supply has been immensely increased as a result of measures initiated by the Government some years ago. Dr. Pisani, however, considers that the natural resources of the islands cannot provide sufficient water for scavenging and flushing drains, and he therefore recommends that sea-water should be used for these purposes. The report contains no special reference to the health of the garrison or fleet. The highest reading of the maximum thermometer was 97 8° F. in September, and the lowest reading of the minimum thermometer was 39 4° in January. From February to September inclusive rain fell on 40 days, the total amount being 4 641 inches; in the four winter months, namely, October, November, December, and January, rain fell on 50 days, the total amount being 9 575 inches. A great seizure was made of over 500 bags of raw coffee berries coated with a mixture of finely powdered plumbago and lead chromate, so that to the untrained eye they did not differ from the best coffee berries. The bulk of this coffee was imported from Trieste, but some of it was traced to Genoa, to Hamburg, and in one instance to London.

"THE NEED FOR CARE IN THE USE OF QUININE IN MALARIAL HÆMATURIA."

To the *New York Medical Record* of Jan. 7th Dr. H. A. Hare, Professor of Therapeutics in the Jefferson Medical College of Philadelphia, contributes a sensible paper on the above subject as a friendly criticism of a special article by an anonymous writer in the *Medical News.* Dr. Hare's object is in no way to disparage quinine or to deny its immense usefulness in malarial disease, but to enter a protest against its indiscriminate use and to show that the caution which Koch has lately given with reference to its use in malarial hæmaturia is well justified and had indeed been given before by many writers in America and especially by physicians in the Southern States. As long ago as 1892 Dr. Hare investigated the views of physicians in those parts of the United States where the mortality from malaria is greatest and reported the results to the Association of American Physicians. He thought himself "justified in stating that quinine is often useless and harmful in the bloody urine of malarial infection, although circumstances might exist in which the drug might be used." He did not go so far as to deny that in some cases of hæmoglobinuria the frequency of the paroxysms might be such as to make the administration of quinine necessary, the kidneys being flushed out by diuretics such as the vegetable salts of potassium. Here the quinine is given because the danger of the continued attacks is greater than that of renal involvement from the drug. He says that everyone admits that malarial poisoning does cause nephritis. A committee of the Tri-State Society of Alabama, Tennessee, and Mississippi found nephritis in all cases of fatal malarial hæmaturia; so did Ralfe. Kiener and Kelsch have found glomerulitis. He further shows that according to writers of experience quinine in full doses has similar effects, producing renal congestion and inflammation. He instances several cases of hæmaturia from its use. The general result of Dr. Hare's paper is to show that quinine is to be used "with brains" if the best results are to be attained and that its routine use in blissful ignorance of its dangers ought not to be advocated, while on the other hand, no one for a moment would cast discredit on a truly specific remedy.

WORKMEN'S COMPENSATION ACT.

THIS Act has only been a little more than six months in operation, yet statistics show that the number of fatal accidents in industrial employments brought forward for compensation in that time have increased by 12½ per cent. and of non-fatal accidents 43 per cent. Numerous difficulties have arisen, notably in those cases in which a man who has been the victim of some chronic disease meets with an accident and dies shortly afterwards; was death due to the disease or the accident? A case of this kind was recently before Judge Meynell at the Sunderland county court. A shipwright named John Cairns while working for Messrs. John Blumer and Co., shipbuilders, of Monkwearmouth, while in a stooping position received on the right loin a blow from a hammer which fell from a staging above. He was at once removed to the hospital but never recovered sufficiently to be discharged. About the sixteenth day after his admission his condition underwent a change for the worse and he died exactly a month after the casualty. His dependents claimed compensation for his loss. The claim, however, was disputed on the ground that death was due to disease and not to the accident. There seems no doubt that at the time of the mischance the man was not in sound health. Several medical men were called on both sides, those for the plaintiffs maintaining that although kidney disease might have been present, yet the blow was responsible for the disease proving fatal, whilst the expert witnesses for the defence alleged that death was attributable to "pneumonia due to chronic disease of the kidneys." Such cases offer a formidable demonstration of the fertility of the field for expensive litigation afforded by the Act. Numerous instances of a similar kind can be imagined: a man suffering from chronic bronchitis and emphysema breaks a rib and dies; a man suffering from chronic pulmonary tuberculosis shortly after lifting a weight has a fatal attack of hæmoptysis, and so forth. From this point of view the Act is likely to be disastrous to men who depend for their livelihood on their employment and who are the victims of some chronic disease which in itself may not threaten life for a considerable period but who are capable of doing a very fair amount of work. For if several cases of the kind just quoted are brought into the courts the masters will be obliged to protect themselves with the result that medical certificates will be required by them from the men certifying that the latter are perfectly healthy and not the subjects of any form of disease. It is to be hoped that efforts which are now being made to induce the legislature to modify the Act will be successful.

THE REFLEX MECHANISM OF THE BLADDER.

THE researches of various experimenters have established the fact that the expulsive efforts of the bladder can be excited by stimulation of sensory nerves, so that, as von Zeissl has shown, contraction of the bladder can be induced not only directly by stimulation of the nervus erigens but also in a reflex manner by stimulation of the sciatic nerve. The evacuation of the contents of the bladder is not, however, quite so simple as it at first sight appears to be, and it is now generally admitted that two distinct factors are in operation—a motor influence which causes contraction of the bladder and increased pressure on its contents, and an inhibitory influence which causes relaxation of the sphincter vesicæ and permits the fluid to escape. As a rule the two events occur simultaneously or nearly so—the detrusor urinæ represented by the body of the bladder contracting and the sphincter vesicæ situated at the neck of the bladder relaxing; but it is a matter of common experience that the two actions may not work harmoniously. The detrusor may contract vigorously yet no urine may be discharged because the sphincter does not relax and on the contrary the detrusor may remain flaccid and yet the urine may escape because the sphincter relaxes. The subject has been taken up by Dr. Alfons Hanc whose observations were made in Professor von Basch's laboratory and are recorded in the tenth number of Vol. LXXIII. of Pflüger's *Archiv*. Dr. Hanc proposed to himself to study and analyse with greater precision than has hitherto been practised the motor phenomena of the reflex act and the influence exerted upon it by different poisons. With this object in view he injected a definite quantity of fluid into the bladder previously emptied of its contents and then applied an electric stimulus of uniform strength to the sciatic nerve. The animal which was the subject of the experiment was placed under the influence of curara to prevent the disturbing influence of muscular movements. In addition, in each experiment the commencement of the action of the detrusor was determined by the rise of a manometer one limb of which was inserted into the bladder and the commencement of the relaxation of the sphincter was determined by the quantity of fluid discharged in a unit of time. The latent period of the two muscles proved to be very different. The latent period of the detrusor—that is to say, the reflex time which elapsed between the application of the stimulus and the rise of pressure of the fluid in the bladder—is itself not always the same. In general it amounts to about one second but in some instances it is as much as two or even four seconds. The latent period of the sphincter is almost always greater than that of the detrusor and there does not appear to be any direct relation between the two, the interval varying from 1·03 to 5—that is to say, the postponement of the discharge of urine after commencing contraction of the detrusor is very variable. In not a few instances the sphincter opened or relaxed more quickly with low pressure in the bladder than with high, which clearly proves that the discharge of fluid from the bladder is independent of the amount of pressure in the bladder. On experimenting with various poisons he found that after injection of morphia in the course of a quarter of an hour the reflex expulsive action of the detrusor was preserved, whilst the depressor or relaxing action on the sphincter was lost The blood pressure remained unaltered Similar results were obtained with chloral hydrate After the ingestion of five grammes of a 10 per cent solution of chloral hydrate the sphincter reflex was abolished whilst the detrusor reflex, slightly weakened, was preserved and the blood pressure was sustained Atropine weakened the reflex action of both the detrusor and the sphincter, hence with some increase in the manometric column showing the pressure exerted by the detrusor on the contents of the bladder there was a diminution in the discharge owing to inadequate relaxation of the sphincters These three poisons belong to the group which rather depress than excite the nerve centres The next poison with which Dr. Hanc experimented was strychnia which strongly stimulates the nerve centres and the effects of which he thought were of special importance to determine since it is so often administered in cases of disease of the bladder He found that sometimes it causes an increase of the reflex action both of the detrusor as manifested by increase of intravesical pressure and also of the sphincter manifested by increased outflow, the former action being more marked than the latter In other instances it abolished the reflex on the sphincter completely whilst that on the detrusor was maintained, and in still another case the sphincter dilated without previous contraction of the detrusor though this latter action followed some time subsequently The effects of muscarin and of nicotin are complicated, for muscarin acts so to speak spontaneously—that is without reflex stimulation—and it acts in this way both on the detrusor and on the sphincter and we must refer to the original article for the further details of its action He considers that it certainly supports the view of the independency of the action of the detrusor and of the sphincter The phenomena observed in animals under the influence of nicotin lead to the same conclusion The whole results of his experiments tend very clearly to prove the distinctness of the motor and inhibitory centres which control the act of micturition

"LIFE IN A FRENCH COD-FISHING FLEET"
